

Bequeathed to the  
Department of Applied Chemistry  
University of Toronto

by the late

Harry Goulding Akers, B. A. Sc.,

a graduate of the

Faculty of Applied Science and Engineering, University  
of Toronto, in the Class of 1909.

Died at Yorktown, Virginia, April 21, 1917.

Digitized by the Internet Archive  
in 2011 with funding from  
University of Toronto

# Journal of the Society of Chemical Industry.

INDEX OF VOL. IV.—1885.

## INDEX OF AUTHORS' NAMES.

	PAGE		PAGE
Abbott, R. B. Treatment of Iron .....	225	Baker, H. B. Combustion in Dried Gases .....	268
Abel, F. A. Carbon in Iron and Steel .....	284	Combustion in Dried Gases .....	268
Abieh, Russian Petroleum .....	71	Baleke, Malt Kilns .....	596
Aclair and Thomson. Phosphates from Slags .....	229	Baldy. See Jean and Baldy .....	508
Adams. See Penny and Adams .....	99	Ballabene, Nitrocellulose (illus.) .....	566
Adams, S. Self-sealing Mouthpieces for Gas Retorts .....	201	Ballard, Chlorimeter .....	311
Agricultural Chemists' Association, Philadelphia .....	290	Bamberger, E. Colour Reaction of some Ketones .....	370
Agricultural and Horticultural Association. Manures at Inventions Exhibition .....	565	Bamberger, E., and Hooker, S. C. Retene .....	394
Akester, W. H., Mitchell, R., and Kelly, R. R. Secondary Batteries .....	751	Bamberger, E. and Kranzfeld, J. Chrysene .....	583
Akitt, Bromine Absorptions .....	98	Bang, J. A. F., and Ruffin, M. C. A. Purification of Alcohol .....	506
Alexander, J. Cooling Furnace Gases (illus.) .....	217	Bang and Sanguinetti. Extraction of Fats (illus.) .....	332
Alexander, J., and Co. Toilet Soap at Inventions Exhibition .....	563	Banks, J. M. Plating Silver with Gold .....	746
Alexander, N. A. Waterproof Cloth and Paper .....	532	Barbaglia, G. A. Alkaloid in Box Tree .....	243
Allan and Hanbury. Malted Food .....	567	Barbe, M. C. P. Sugar Manufacture .....	748
Allen, Estimation of Urea .....	495	Barbet, E. A. Rectification of Alcohol .....	402
Allen, A. H. Applications of the Nitrometer (illus.) .....	178	Barclay, H., and Simpson, R. Treatment of Fine Dust .....	351
Gas Analysis Apparatus (illus.) .....	156	Barff, F. S. Preserving Food .....	362
Applications of Nitrometer .....	117	Barlow, S. Combined Paper and Cloth .....	454
Allen, R. See Burch and Allen .....	223	Barnes, J. Titanic Acid as a Mordant .....	310
Allen, T. Lucifer Matches .....	117	Barns. See Strouhal and Barns .....	222
Allihn, F. Double-action Wash Bottle (illus.) .....	65	Barrett, A. Polishing Printing Rollers .....	250
Filtration with absence of Air (illus.) .....	368	Barth, G. Apparatus at Inventions Exhibition .....	568
Alloft, J. B. Treatment of Wet Refuse .....	355	Barth, M. Glycerine in Wine .....	292
Allison, H. J. Artificial Stone .....	355	Barth and Wedel. Condensation Products of Resorcinol .....	50
Alteneck, v. H. Standard of Light .....	462	Bartsch, C. Conc. Sulphuric Acid (illus.) .....	590
Amthor, C. Caramel .....	361	Basse and Selver. Manufacture of Nickel and Cobalt .....	405
Anastasi, A. Biography of Leblanc .....	172	Bassett, See Magowan and Bassett .....	348
Anderlini, F. Fractional Distillation .....	511	Batho, W. F. Basic Lining for Furnaces .....	224
Anderson, A. W. White Lead .....	351	Bath, J., and Co. Hard Glass at Inventions Exhibition .....	560
Anderson, W. Purification of Water .....	133	Bauer, T. Coke Ovens .....	551
Purifying Water .....	263	Bauer, M. Meat Powder .....	486
Purifying Water .....	546	Baumann, Salicylic Acid .....	688
Anderson, W., and Ogston, G. H. Purification of Water by Iron (illus.) .....	544	Baumann, A. Behaviour of Zinc Salts towards Plants .....	408
André, G. G. Explosives .....	753	Baumann, T. See Noelling and Baumann .....	397, 308
Secondary Batteries .....	547	Baumert, G. Detection of Arsenic .....	459
André, J. Paper Making .....	241	Baumhauer, Alcohol Tables .....	554
Andrews, G. J., and Sutton, J. E. Paint for Ships' Bottoms .....	124	Baumhauer, E. H. v. Thermostat and Registering Thermometer (illus.) .....	368
Anschutz, R. Vacuum Desiccator (illus.) .....	612	Baxter, W. See Mackay .....	679
Anthony. Density of Solutions of Sulphurous Acid .....	305	Bayer, F., and Co. Isatin .....	203
Aowers, H. Pseudocumidine .....	739	Beck, E. O. Disinfectant .....	415
Pseudocumidine .....	293	Beck, W. H. Colouring Paper in endless rolls .....	43
Arche, A., and Hassack, C. Indian Bronze .....	57	Becker, F. See Wagner and Becker .....	412
Armstrong, H. E. Discussion on Russian Petroleum .....	622	Beckett, W. See Hargreaves, Beckett and Cliff .....	253
Discussion on Heating by Radiation from Flame .....	622	Beckurts, J. Fly-dusts, free from Arsenic .....	281
Coking Coal .....	451	Beckurt, Detection of Arsenic .....	551
Discussion on Gelatine Process of Water Examination .....	709	Bedson. Gas from Wiclieszka Mine .....	651
Armstrong, J. Extract of Hops .....	133	Bedson, P. P. Gas from Borings at Middlesborough .....	650
Arnold, C. Estimation of Nitrogen .....	370	Behal, A. Separation of Copper and Cadmium .....	552
Vegetable Parchment .....	609	Behr, A. Cellulose and Glucose from Wood .....	507, 551
Arrol, W., and Melkie, J., jun. Ammonia Salts (illus.) .....	118	Behrend. Sprouted Barley .....	538
Asby, E., and A. Treatment of Fumes from Cement Kilns .....	415	Melting .....	412
Asipov, W. Treatment of Sewage .....	463	Behrin, A. Manufacture of Paper-pulp (illus.) .....	241
Atherley, R. J. Amalgamating Gold .....	224	Beilby, G. Gas Thermometer (illus.) .....	40
Atwater, W. O. Absorption of Nitrogen by Plants .....	362	Purifying Paraffin Oils .....	584
Aubert, W. Aerating and Storing Beer .....	546	Cooling Oils for Extraction of Paraffin .....	653
Austin, J. B. Disinfectant at Inventions Exhibition .....	474	Separation of Paraffin from Oils .....	488
Disinfecting Powder .....	240	Cooling Oils for Extraction of Paraffin (illus.) .....	484
Avery, C. E. Logwood .....	585	Discussion on Destructive Distillation .....	329
Ayden. Liquid Fuel .....	78	See Young and Beilby .....	275
		Beilstein. Petroleum Lamps .....	198
Bachmeyer, W. Filtration and Drying of Oxidisable Precipitates (illus.) .....	369	Beilstein and Kogler. Pseudocumene .....	278
Badische Anl. u. Sod. Fab. Thallio .....	410	Beils H. and J. F. Liquid Carbolic Acid (illus.) .....	314
Dyes at Inventions Exhibition .....	479	Carbolic Acid .....	416
Baessler, P. See Noble and Baessler .....	464	Pend. Conc. Furnace Gases (illus.) .....	219
Baeyer. Hydration Types .....	9	Lebed, J. F. P. Hydrate Gases .....	200
Constitution of Indigo .....	63	Pe. Proc. Ammonia Soda Process .....	527
Baeyer, A., and Lazarus, M. J. Isatin Derivatives .....	711	Lebed, J. F. Treatment of Gaseous Tar .....	337
Baeyer and Debusen. Nitrocinnaaldehyde .....	710	Treatment of Oils and Tars from Tar .....	571
Bailey. Solubility of Nitric Oxide in Sulphuric Acid .....	417	Coke Ovens .....	169
Baker. See May and Baker .....	569	Leil, H. Gas from Borings for Salt .....	650
Baker, H. Orthovanadates .....	688	Leil, J. L. Discussion on Carbon in Steel .....	286
		See of Iron in Blast Furnaces .....	216
		Leil, J. See Laving and Leil .....	327
		Leil, R. Furnace for Distilling Shale .....	337

	PAGE		PAGE
Bellamy, F. Action of Metals on a Mixture of Acetylene and Air.....	608	Boulvard, Chlorine Manufacture.....	536
Belli, Azoxybenzene.....	710	Boult, A. J. Gas from Hydrocarbons.....	268
Benckiser, T. See Nietzki and Benckiser.....	276	Boult, Gas Manufacture.....	201
Benedikt, R., and Zsigmondy, K. Estimation of Glycerol.....	610	Boulton, J. O. See Perry and Boulton.....	158
Benedikt, See Weselsky and Benedikt.....	52	Boulton, See Burt, Boulton and Haywood.....	171
Bennett, J. A. B. See Walker and Bennett.....	129	Bourdon, K. Burette (illus.).....	689
Bent, S. Byrom and Bennett.....	129	Boutaud, Absorption of Nitrogen by Leucaminose.....	601
Bennie, G. Extraction of Oil from Bituminous Rock.....	186	Boutigny, Report for Extraction of Bitumen (illus.).....	18
Benoist, L. See Cullin and Benoist.....	493	Bower, H. Bichromate of Potash.....	214
Berens, Mixings for Glass.....	500	Bower, G. Ruchrome, etc., at Inventions Exhibition.....	463
Berensmann, R. Examination of Fats (illus.).....	535	Bowers, H. J. A. Softening Water for Boilers.....	193
Turkey-red Oil.....	115	Bowler, Ammonia Soda Process.....	529
Bente, F. Removal of Bitterness from Lupines.....	407	Bowman, Structure of Cotton Fibre.....	10
Bent, S. Wood Tar.....	104	<i>Boviside Company</i> , Artificial Ivory.....	517
Berard, G. H. Utilization of Peat Fibre.....	673	Bowman, Artificial Ivory.....	517
Berdoe, See Griffiths, Berdoe and Co.....	563	Branhall, C. Smelting Furnace.....	223
Berend, L. Trimethylquinoline.....	291	Bramley, W. See Cochrane and Bramley.....	401
Beresford, J. A. See Walker and Beresford.....	111	Brand, Crucibles for Steel.....	498
Biergh, A. T. Waterproof Paints.....	259	Brandes, Large-grained Salt.....	292
Biringer, J. J. Ueber.....	107	Brass, See Wallach and Brass.....	292
Birner, See Iery.....	466	Brasse, L. Amalgam in Leaves.....	151
<i>Birdorfer Metallwaaren Fabrik</i> , Malleable Nickel and Cobalt.....	221	Braun, F. Dyeing Fabrics without Stretching them (illus.).....	580
Birnsthen, Nitrotoluidines.....	111	Braun, H. Fireproof China at Inventions Exhibition.....	260
Birnsthen, A. Methylenic Blue, etc.....	276	Braun, W. Purification of Copper.....	352
Birnsthen, A., and Seipner, A. Jaglone.....	292	Copper Refining.....	676
Birtheit, Velocity of Explosion.....	309	Bray, H. de, and Rosetti, C. H. Combustion of Liquid Fuel.....	582
Birz, J. Compositive Testes by Heat.....	458	Bray, H. de, and Rosetti, C. H. Combustion of Liquid Fuel.....	582
Birther, English Flint Glass.....	501	Bray, H. de, and Rosetti, C. H. Combustion of Liquid Fuel.....	582
Bertschinger, A. Acidity of Beer.....	685	Bremer, M. O. Printing Blue Grounds.....	493
Berzelius, Pyrosulphates.....	281	Breuer, O. Starch as Substitute for China Clay in Printing.....	312
Berzelius and Rose. Action of Sulphur Compounds on Lime.....	671	Printing Blue Grounds on Wool.....	312
Best, T. F. Artificial Ivory, Horn, etc.....	721	Brevort, H. L., and Roberts, J. L. Electric Batteries.....	751
Bevan and Cross, Wood Tar.....	151	Breyer, F. Asbestos Felt.....	530
Bevan, E. J. See Cross and Bevan.....	7	Briggs, J. See Glass and Briggs.....	390
Bevan, See Cross and Bevan.....	327	Brian Freres, Oxygen Apparatus at Inventions Exhibition.....	568
Beyer, C. Homologue of Quinoline.....	326	Brisson, C. Distillation of Nitrogenous Liquids (illus.).....	670
Beyer and Kegel, Dinitrophenol Sulphonic Acid.....	203	<i>British Alizarin Co.</i> , Inventions Exhibition.....	171
Naphthosulphonic Acids.....	379	Brito, P. S. Detection of Iodine in presence of Bromine.....	297
Biddle, W. C. A. Enamelling Iron, etc.....	579	Brochner and Co. Naphtolsulphonic Acids.....	50
Bidder, Liquid Fuel.....	78	Brooke, R. Explosives.....	753
Biechle, Rhenish Cresote.....	151	Brooks, J. L. Fireproof China at Inventions Exhibition.....	260
Biedermann, E., and Harvey, E. W. Utilization of Furnace Gases.....	737	Copper Refining.....	676
Biefel, Poisoning by Gas.....	608	Brooks, J. L. Tartar Emetic Substitute.....	207
Billings, A. W. Beer Manufacture.....	685	Brothers, H. E. See Smith, Watson.....	738
Billington, C., and Newton, J. Manganese Alloys.....	287	Brousson, H. F. Preservation of Moist Colours.....	289
Bindewald, See Zincha and Bindewald.....	395	Brown, Campbell, Discussion on Chemical Technology.....	83
Bindschedler and Busch, Azoresorfinol.....	50	Brown, J. Campbell, Discussion on Rivers Pollution Bill.....	167
Birch, R. W. P. Pollution of Thames below London.....	515	Brown, J. Campbell, Discussion on Rivers Pollution Bill.....	167
Bischof, G. Discussion on Proposed Rivers Pollution Bill.....	6	Brown, D. A., and Briggiani, C. F. Asbestos Compound for Roofing, etc.....	284
Natural Gas.....	39	Brown, C. Discussion on Treating Liquids with Gases.....	643
Spongy Iron.....	361	Brown, F. Carbonates of Potash and Soda.....	117
Bischof, C. Coloured Clays.....	103	Brown, H. T., and Morris, G. H. Action of Diastase on Starch.....	682
Bischof, Discussion on Gelatine Process of Water Examination.....	707	Brown, I. Mill for Phosphates, etc.....	131
Bishop, A. W. Filtration of Water.....	707	Preparing Lime for Agricultural Use.....	131
Bittmann, See Reichardt and Bittmann.....	607	Brown, J. Disinfecting Powder.....	210
Black, W., and Larkin, T. Furnaces for Soda, etc.....	212	Brown, W. C. See Brown, F.....	117
Blackman, H. Parker and Blackman.....	1263	Brown, W. H. See Seymour and Brown.....	121
Blakie, A. Obituary.....	493	Buck, F. Coke Oven (illus.).....	485
Blair, A. A. Valuation of Acetate of Lime.....	497	Buck, F. Coke Ovens.....	485
Blanc, S. J. Fireproof and Weatherproof Paints, etc.....	536	Brunner, J. C. Capitaine.....	581
Blank, A. See Knorr and Blank.....	62	Brunner, Discussion on Chemical Technology.....	89
Blank, H. Carbonisation of Wood (illus.).....	271	Brunner H. Discussion on Rivers Pollution Bill.....	168
Blattner, G. Decomposition of Sulphate of Ammonia by Sulphate of Soda.....	313	Treatment of Phosphates.....	594
Blount, B. Cause of Decrepitation of Explosive Pyrites.....	671	Brunner, H., and Chuard, E. Beta-Anido-alizarin.....	278
Blum, Recovery of Phosphoric Acid.....	506	Brunner, H., and Krammer, C. Azoresorcinol and Azoresorcinol Sulphonic Acids.....	50
Blunoski, M. See Julken, M.....	717	Midophenol Sulphonic Acids.....	51
Byth, H. G. White Lead.....	227	Brunner, H., and Robert, W. Colouring Matters from Phenols.....	276
Boake, A., and Co. Sulphurous Acid Products at Inventions Exhibition.....	521	Brunner, K. See Krafft and Brunner.....	406

## INDEX OF SUBJECTS.

	PAGE		PAGE
Accumulators	608, 609	Amalgamation of Gold and Silver	678
Electric	751	Process for Silver and Gold	303
Acetanilide, Nitration in presence of Sulphuric Acid	329	Ambulance Box for Chemical Works	34
Acetic Acid, Manufacture of Pure	641	Amido-groups replaced by Chlorine, etc., in Aromatic Compounds	204
Acetoumidine	189	Amidoazo Colours	150
Acetone, Action on Aniline	710	Amidoazobenzene	740
Acetothienone	202	Amidobenzophenones	204
Acetylene and Air, Influence of some Metals on	668	Amidocresol	710
Acetylnitroumidine	710	Amidophenol Sulphonic Acids	51
Acetylthioxen	729	Amidotetraethylbenzene	459
Acid Powder for Cleansing, etc.	510	Amines, Chloral-hydrate with Tertiary	398, 491
Acidimetry	510	Mononitrophenols from	398
Acids, Action on Glass	215	Prepared from Phenols	276
From Purification of Naphtha, Utilisation of	583	Quinones from Parameethylated	489
Vessel for	497	Ammonia	594
Address to Glasgow Section, Chairman's	630	Action on Solutions of Potassium Salts	323
President's, at Fourth Annual Meeting	497	From Blast Furnaces	737
Adrianople Red	18	From Blast Furnace Gases	737
Adulteration of Olive Oil Detected	601	Used in Distillation of Coal	270
African Peach Root	570	From Furnace Gases (illus.)	217
Agricultural Experiments	126, 127	From Gases	198, 332
Air, Apparatus for Carburetted (illus.)	106, 111	Nitrate protected from Deliquescence	317
Compressor for Gas Burners	110	Preparation of	401
Estimation of Oxygen in (illus.)	295	Recovery from Ammonia Soda Liquors	458
Oxygenated	136	Soap	633
Thermometers (illus.)	10, 11	Soda Process	457, 458, 526, 527, 595
O Towns, Sulphurous Acid in	133, 162	Soda Process (illus.)	208
Albumenoids in Barley	377	Soda Process, Treatment of Liquors from	211
Changes produced in, by Steaming	414	Sulphate	212
Alcohol, Action on Diazo-compounds	275	Sulphate Manufacture	315
Estimation of Methyl-in presence of Ethyl-	291	Sulphate from By-products of Paraffin	171
From Jerusalem Artichokes	162	Sulphate, Treatment of	211
Manufacture	506	From Gas-liquor (illus.)	112
Rectification of	162	Obtained during Recovery of Tin	401, 406
Alcohols, Reaction of Secondary	120	From Furnace Gases	111
Aldehydes, Reaction of	120	Extraction from Coal-gas	49
Algini	391	Colours fixed on Cotton by means of (illus.)	33
And its Compounds	518	Salts Manufacture (illus.)	118
Algulose	391	Ammoniacal Liquor, Treatment of	273
Alizarin	135	Ammonium Carbonate, Oxidation of Copper in presence of	677
By Amido-	587	Chloride	117
Compounds of Aluminium with	18	Chloride Decomposed by Carbonate of Lime	709
On Cotton	397	Sulphate Decomposed by Sodium Sulphate	343
Electrolytic Production of	310	Sulphate, Effect on Beet	129
Test for Alumina	673	Superphosphate as a Manure	129
In Wool Dyeing	634	Ammonium	558, 561
Alkali determined in Soap	634	Amyl Acetate as Photometric Standard	262
Loss caused by Sulphurous Acid in Loblane Process	31	As a Solvent for Nitrocellulose	289
Waste, Discussion on Sulphur Recovery	173, 522	Amylase present in Leaves	460
Waste, Sulphur from	198	Anesthetics	552
Waste, Utilisation of	198	Analysis, New System of Volumetric	755
Alkalimetry, Indicator for use in	137	Of Soap	631
Alkaline Phosphates and Silicates, Manufacture of	214	Analytical Notes in France in 1884	310
Residues, Treatment of	117	Anhydrides, Formation of Organic	329
Alkalis on Cinchonine, Action of Caustic	688	Aniline, Action of Acetone on	710
Indicators for Caustic	552	Black	296, 591, 592
Tetraphosphates	593	Black, Development of	493
Alkaloids, Compounds of, with Chloride of Iodine	687	Colours at Inventions Exhibition	176, 177
At Inventions Exhibition	569	Ortho-nitro-	276
In Lupine	538	From Tannic Liquor	171
From various Lupins	602	Ortho-nitro- Absorption of Bromine by	398
Alkanet, Identification of	611	Anthracene	432
Alloy for Coating Metals	245	Dimethyl-	272
For Electrical Conductors	507	Formation of	375
Alloys, Metallic	286, 287	From Petroleum Residues	79
Alum from By-products of Paraffin	471	In Tar from Water Gas	336
Process of Clarifying Sugar	566	Anticorrosive in France in 1884	215
Solubility in Solutions of Sulphate of Alumina	402	Anthraquinone	429
Alumina, Alizarin Test for	310	Antifouling Composition	432
In Cements, Estimation of	215	Antimonial Mordants	313
Combined with Oxalic Acid	491	Antimony, Absorption of Bromine by	37
And Lime Phosphates	497	Compounds used in Dyeing and Printing	613
Manufacture	345	Ores, Treatment of	332
Mordants	586, 587	Ores, Extraction of Gold from	29
Permanganate of	463	Oxalate used in Printing	433
Process of Clarifying Sugar	541	Oxalate, Value as Mordant	400
In Ceramics, Estimation of	245	Potassio Oxalate of, as Substitute for Tartar Emetic	207
Aluming Hides or Skins	717	Smelting Sulphide of	678
Aluminium, Absorption of Bromine by	97	Sulphide, Treatment of Ores containing	123
Bronze	224	Antipyrene (a Febrifuge)	60
Chloride, Action on Hydrocarbons	270	Anti-Scrap (decomposition Preventative)	153
Chloride, Syntheses effected by use of	114	Antiseptic Compound	439
Extraction	121, 679	Mixture	463
Fluoride, Manufacture of	741	Antiseptics, Activity of	517
Glass, etc., coated with	245	Aromatic Compounds, Influence of Light in Action of	398
Manufacture	319, 104, 601	Halogens on	111
Sulphate, Density of Solutions of	402	Compounds, Synthesis	111
Alizarin, etc., prepared for Printing	280		
Amalgamating Apparatus	122		
Process	351, 352		

	PAGE		PAGE
Aromatic Diamines, Nitroso-derivatives of	326	Beet-roots, Pulping Machine for (illus.)	233
Orthodiamines, Reagent for	511	Beets, Machine for Washing (illus.)	233
Sulphonic Acids of	581	Benzal Lights, Magnesium for	389
Arsenic, Absorption of Bromine by	592	Benzaldehyde Compounds with Aniline Hydrochloride	395
Acid	592	Benzene, Action of Chlorine on	113
Detection of	551	From Coal, etc.	338
Hydrochloric Acid free from	281	From Coke Oven Gases	488
Poisonous Effect on Vegetable Organisms	461	Derivatives from Coal Gas	475
Pyrites free from	333	Derivatives from Potassium Carboxide	616
Removed from sulphuretted Hydrogen	403	Determination in Naphtha	616
Zinc freed from	281	Dibromothiophen from	583
Arsenical Compounds Removed from Ores	459	From Furnace Gases	531
Ores of Cobalt, Treatment of	120	Perchloro-, Perchlorophenol from	270
Artemisia, Quinine Alka loids in (illus.)	136	From Petroleum Residues	79
Asbestos as a source of Santolol	469	Benzene, Action of Chlorine in Commercial	269
Art-holke, Utilisation of Jerusalem	462	Benzidine, Potencu Derivative	398
Asbestos, Compound for Roofs, &c.	281	Benadinedisulphonic Acid, Colours from Tetrizo-	52
Lining for Acid Drains	497	Benzoic Acid in Coal Tar	335
Membrane for Filter	530	Benzoyl-ecgonine	509, 752
Ascension Pipes of Gas Retorts (illus.)	107, 110	Benzoylsulphimide, A substitute for Sugar	608
Asphalt	688	Benzylidenediamitypyrine	61
Asphaltic Rocks, Products from	183	Benzyl-narceine	508
Astakki (Petroleum Residue)	75, 111	Benzyl Violets, Sulphonated	205
Atmospheric Air, Production of Oxygen from	568	Bessenerising (Copper Ore)	502
Auramine	432	Beverage Made from Clover	462
Auramines	279	Non-soluble	183, 362
Aurin	136, 431	Non-intoxicating (l)	507
Aurin Derivatives	279	Bistre, Phenylhydrazine as Discharge on	207
At Inventions Exhibition	476	Bisulphites, Action on Chlorates	206
Aurophenylene	475	Combination of Azo-compounds with	492
Azo-colours	338, 435, 452	Bituminous Rocks, Extraction of Oils from (illus.)	182
From Beta-Naphthylamine	35	Bix, Brellana, Colours from	115
Separation of	279	Bixin	115
Silk Dyeing with	591	Black Ash Waste employed to Deodorise Sewage	463
Brominised	50	Black on Cotton, Dyeing	207
Azo-compounds combined with Bisulphites	192	Dyed on Cotton	592
Azonaphthalene	670	Pigment from Shale	536
Azonitrolic Acids, Reduction Products of	491	Black on Glass	602
Azoresorelin	50	Varnish for Leather	687
Azoresorufinol	50	Blast Furnaces	121
Diacetyl-	50	Analysis of Zinc Dust from	138
Azoline (an Explosive)	366	Fuels for	216
Azotometer	124	Blast Furnace Gas, Analyses of	221
Azoxybenzene	710	Regeneration of (illus.)	221
Dinitro-	711	Blast Furnace Working	677
Azoxytoluene	711	Blasting, Cartridges for	417, 418
Azuline, Yellow Dye from	279	Blasting Powder from Nitrocellulose	243
Azurophenylene	475	Blasting, Submarine	366
Azy-lines	397	Bleaching	312, 313, 100, 401, 491
Bacteria, Yeast free from	506	Apparatus for	155
Battle-plates for Flues (illus.)	56	Dyeing, etc., Hanks of Yarn	280
Baking Powder	116, 514	Fibres, etc., for Pulp	686
Baltic Region, Constitution of Soils of	209	Fibres and Pulp	712, 713
Barium Hydrate (illus.)	209	Machine	322
Manufacture	715	Paper, Behaviour of Solutions of	455
Oxide	314	Solution	587
Barks, Tannin in Various	264	Straw	492
Barley	506	Wood Fibre	492
Analyses	515	Yarn, etc. (illus.)	673
Experiments on Growth of	126, 130	Blends, Furnaces for (illus.)	54
Nitrogen in	513	Blood, Determination of Haemoglobin in	511
Nitrogenous Matter in	413	Blood as a Manure	131
Phosphates for	339	Blue Grounds, Printing	493
Spouted	538	On Wool	312
Washing	681	Methyl-	276, 277
Barleys, Comparisons of	412	Blues from Rosaniline	84
Barvta Carbonate, Decarbonating	674	Board Schools, Science in	284
Hydrate, Manufacture	395	Boards, Asbestos Compound for	392
Bastose or Jute Fibre	11	Boiler Chimneys, Construction of	391
Batteries, Electrodes of Secondary	517	Explosions, Causes of	391
Elements for Voltaic	507	Feed Water, Purifying	180
Galvanic	609, 751	For Hops (illus.)	105
Secondary	608, 609, 686	Incrustation Preventive	18
Silico-carbon for	363	Boilers, Corrosion Prevented in	198
Beachwood Tar Products	153	Decrustation Composition for	114
Beer, Acidity of	685	Heated by Flame (illus.)	624
Analyses of Lager	377	Heated by Radiation from Flame	184
etc., Apparatus for Injecting Liquid Carbonic Acid (illus.)	58	Incrustation Preventive for	193, 529
Apparatus for Cleansing	411	Purifying Feed Water for	243, 415
The Breaking of	684	For Wood Pulp	682
Influence of Hops and Yeast on	683	Bone Black, Gas Exit Tube for Retort (illus.)	682
Manufacture	685	Treatment of	159
Wort, Nitrogen in	513	Charcoal, Rectification of	127
Preserving	362	Meal as Manure for Oats	336
Pumps, Cleaning	133	Bones, Carbonising by Superheated Steam (illus.)	226, 227
Red Colouration of	306	Extraction of Fat from	459
The Reddening of White	684	etc., Fat Extracted from	406
Value of Hops in	505	Extraction of	57
Beet Cuttings, Drying	511	Book-binding, Combined Paper and Cloth for	454
Experiments on	110, 411	Borax, Reaction of, with Turnerie	687
Growth of	542	Boric Acid, Influence on Indicators	611
Juice, Filter for (illus.)	231	Boring Tools used for Oil Wells (illus.)	326
Juice, Lime Process of Clarifying	511	Borohydrate for Preserving Food	213
Nematoids	538	Box Tree, Alkaloid in	397
Potash and Lime Salts in	511	Brasslin	750
Preservation of Sections of	411	Breweries, Pollution of Rivers by	114
Beetroot, Cultivation of	355	Brewers' Grains, Value of	205
Experiments on Growth of	127, 129	Brewery Institute of Berlin	376, 685, 825
Molasses, Leucine and Tyrosine in	411	Experiments	543
Beet-roots, Drying Machine for (illus.)	231	Grape Sugar in	542
Manufacturing	231	Liquorice Root in	359

	PAGE		PAGE
Brewing, Treatment of Grain for	114	Carica Papaya, Preparation from	571
Brick Kilns	216	Carmine Manufacture	587
Brick Manufacture	283	Cartridges with Moderated Explosion	733, 734
Bricks, Coating or Surfacing	458	Casene	685
Etc., from Slag	283	Castor Oil, Residue from Distillation of	206
Bromides, Chlorine Determined in Presence of	756	Cathartic Acid	416
Brominated Derivatives of Diphenyl, etc.	662	Cattle Food	567
Bromine Absorptions	96	From Brewer's Grains	567
Bromine, Iodine Detected in Presence of	237	Liquors treated for	258
Phosphorus Acid Oxidised by	576	Sesame Cake as	558
Precipitation of Manganese by	367	Sugar Beet as	58
Valuation of	687	Vegetable Ivory Turnings proposed as	603
Bromostrychnine, Physiological Action of	135	Yttriferous Germs in	461
Bronze, Composition of Indian	37	Cave Earth, Sample of	603
Bronzes, Japanese	57	Cediret, History of	152
Brown Coal, Analyses of	120	Cellulose, Hydration of	7
As Fuel in Blast Furnaces	48	Oxidation of	10
Bruceine	361, 216	Treated for Paper Making (illus.)	211, 212
Physiological Action of	155	Products of Distillation	326
Food Strychnine, Relation between	688	From Saw-wood	519
Building Materials at Inventions Exhibition	500	Utilisation of Liquors from Manufacture of	507
Bullocks, Cost of Feeding	511	From Wood	507
Burette (illus.)	552	Cellulose	752
Stark's Reservoir (illus.)	34	Cement, Adulteration of Portland	319
Burette (illus.)	659	Kilns, Deodorising Fumes from	415
Gas (illus.)	161	Manufacture	101
Burners for Carburetted Gas (illus.)	106	Treatment of Slurry for	101
Butter, Examination of	514	Waterproof	675
Making	131	Cements	119, 120, 215
Making, Defects in mode of	231	Hardening	158
Specific Gravity at 100° C.	601	Hardening of Hydraulic	119
Buxidine, Para-	213	Centrifugal Machine for Laboratories (illus.)	754
		Cerealine in Product from Maize	132
Cabbage, Value as Fodder	126	Chamber Crystals, Sulphuric Anhydride from	116
Cadmium and Copper, Separation of	552	Chambers, Sulphuric Acid, in the United States	27
Calcipotul	292	Champagne Manufacture	507
Calculing Kilns	47	Charcoal, Effect of, on Sugar Syrup	410
Calcium Carbonate, Ammonium Chloride decomposed by	709	From Sea-wood	519
Chloride, Solubility of Calcium Sulphate in solutions of	31	Sugar Manufacture without	511
Chloride Tube (illus.)	368	Water filtered through	703
Chloride, Utilisation of	497	Chemical Industries of the United States	26
Hydrosulphide, Test for Chloralhydrate	511	Works, Refuse Waters of	721
Hypochlorite, Conversion of, into Chlorate	522	Chemicals at the Inventions Exhibition	568, 569
Iodide as an Antiseptic	520	China Sulphate as Manure for Beet	119
Sulphur, Compounds of	503	Sulphate as Manure for Oats	157
Sulphate, Solubility in Saline Solutions	31	Chimney Fumes, Treatment of	363
Tartrate, Valuation	215	Removed by Dynamite (illus.)	371
Calico Printing, Chemistry of	311	Chimneys, Construction of	484
Calorimeter for Fuel	322	Construction of Boiler	392
Camphor, Compressed	500	China Clay, Starch as Substitute for	405
Sublimed Transparent	509	Grass	552
Candles, Aerated	667	Chloralhydrate, Test for	511
Hygienic, containing Iodine	211, 680	With Tertiary Amines	491
Shown at Inventions Exhibition	667	Chlorate of Potash	212
Etc., at Inventions Exhibition	502	Chlorate of Soda as a Discharge for Indigo	524
Machines for Moulding Ends of	150	Chlorates, Action of Bisulphites on	506
Cane Sugar, Circular Polarisation of	132	Action on Metallic Vessels	32
In Wine	291	Manufacture	524
Cannel Coal, Composition of	326	Chloride of Lime, Application of	491
Origin of Phosphorus in	108	Chlorides, Electrolysis of	223
Cannose, Products of Distillation	387	Decomposed by Electrolysis	364
Caoutchouc, Analysis of Vulcanised	254	Chlorides (illus.)	311
Substitute for	236	Chlorindigo	108
Recovery of Waste	236	Chlorine, Action on Boiling Benzene	113
Ash of Vulcanised	511	Determined in presence of Bromides and Iodides	756
Carbon	366	Diphenylamine, a Reagent for	613
Carbonaceous (an Explosive)	366	Evolved by Electrolysis	211
Carbonic Acid	152	Furnace	175
Derivatives at Inventions Exhibition	175	Manufacture	211, 315, 457, 458, 523, 525, 591
Residues, Anthracene from	335	Manufacture (illus.)	212
Carbon, Blocks for Filters	210	Manufacture, Recovery of Oxide of Manganese	498
Bisulphide, Estimation of	553	From Magnesium Oxychloride	175
Combustion with Iron	351	Etc., substituted for Amido-groups in Aromatic Com-	201
Dioxide, Action on Soda Waste (illus.)	114	Chlorine Bases, Colours from	453
Dioxide, Reduction of, by Carbon	487	Chlorocarbonic Ethers, Colours from action of	492
In Iron and Steel	281	Chloroform, Action on Toluene	272
Manufacture of Porous	686	Manufacture	213, 611
Monoxide, Combustion of	668	Chloropierin, Action on Toluene	277
Slow burning	134	Cholera, Communication by Drinking Water	29
Carbonating Furnace	422	Communicated by Water	239
Liquids	553	Choline in Hops	291
Carbonic Acid, Amount decomposed by Beet	255	Chrolithon, Treatment of	600
Action of Liquid on Glass	103	Chromates, Manufacture	211, 213, 214, 221
In Coal Gas	665	Chromate Manufacture	498
Gas, Apparatus for (illus.)	114	Chromates of Soda	554
Manufacture	345, 497, 506	Chrome, Discharge of Indigo Blue	493
Used in Manufacture of Ice (illus.)	736	Green	592
Liquid, Apparatus for injecting into Beer, etc. (illus.)	58	Mordant	312
Liquid	610	Chrome-tanned Leather	365
Liquid (illus.)	311	Chromic Acid Manufacture	204
Preparation of Liquid, at Burgbrohl	713	Chromic Alloys	287, 351
Solid (illus.)	210	Colours	671
Manufacture of Solid	116	Colours on Cotton	115
Saturator and Washer for (illus.)	681	Estimation of	241
Carbonic Oxide, Combustion of	621	And Iron, Alloys of	678
Oxide, Manufacture	392	Mordants	586, 588,
Oxide obtained from Producer Gas	727	And Potashes	71
Carbonising Apparatus for Sawdust, etc.	114	Chromometer for Comparison of Petroleum (illus.)	401
Carbons for Electric Lamps	605	Chrysene	583
For Electric Lamps and Batteries	686	Constitution of	471
Carburettor for Air, etc.	200	Cinchene	61
For Gas, etc.	737	Cinchomeronic Acid	391
Carbylamine in Commercial Benzene	268	Cinchous Alkaloids	61

	PAGE		PAGE
Cinchonamine	571	Compressing and Exhausting Apparatus (illus.)	757
Cinchonidine in Quinine, Determination of	551	Compressor for Gases	197
Cinchonine, Action of Caustic Alkalies on	688	Concentration of Liquids (illus.)	241
Chloride	61	For Dilute Solutions (illus.)	251
Cinders, etc., Metals extracted from	223	Concrete, Hygienic	415
Cinnamaldelyde, (Ortho and Pararotro)	540	Condenser (illus.)	737
Cinnamic Acid, Paracarboxyl	306	For Coal Gas	200
Nitrocarboxyl	326	For Naphtha, etc. (illus.)	196, 475
Citric Acid examined for Tartaric Acid	552	For Spirits	238
Test for	369	Conhydric, Action of Hydrochloric Acid on	592
Clarifier for Water, etc.	536	Conducting	292
Clay, Drying	283	Cone Group	292
Formation of Coloured	103	Reactions of	688
Preparation of	282	Continuous Sheets of Lead, etc., Machine for	122
Presses for Moulding (illus.)	318	Converters, Tuyeres for	123
Treatment of	281	Cooling, Extraction of Paraffin by (illus.)	321
Cloth and Paper combined for Bookbinding	151	Furnace (illus.)	219, 220
Waterproof	532	Machine for Separation of Paraffin	226
Clover, Beverage made from	162	Machine	459
Experiments on Growth of	130	And Moulding Machine for Soap	633
Coal, Analyses of Brown	48	Copper and Cadmium, Separation of	552
Arrangement for Burning	111	Coated with Lead	678
Carbonising	290	Cotton	503
Composition of	108, 325	Electrolytic Extraction	600, 601
Compressing	669	Electrolytic Precipitation of (illus.)	296
Distilled with Ammonia	273	Extraction of	352
Dust, Explosion of	268	Extraction in the United States	29
Dust, etc., Gas from	333	Furnace for	225
As Fuel in Blast Furnaces	216	Ac Mangrove Alloy	287
Heat of Combustion	450, 187	Matte, Treatment of	225, 352
Mined in France in 1881	582	Ores, Treatment of	121, 401, 502
Mines, Explosions in	186	Oxidation of	286, 677
Mines, Gas Indicator for use in	716	Oxide, Decomposition by Heat	286
Origin of Phosphorus in	108	For Estimation of Sulphuretted Hydrogen	608
Products of Combustion	486	Precipitation by Iron (illus.)	728
Proximate Constituent of	392	Recovery from solutions	225
Separating Products of Distillation	200	Refining	676
Utilisation of Waste	201	Treatment of	252
Washing and Drying	109	Working Auriferous and Argentiferous Ores	288
Coal-gas, Ammonia Extracted from	49	Corrosive Material for Paper Mache, etc.)	508
Ammonia from	332	Cotton, Aluminic Mordants on	566
Analysis of	665	Black, Dried on	592
Caloric Power of Diluted	582	Cake as Food for Cows	127, 129
Carburetted	190	Cake, a Sugar from	411
Composition of	326	Cause of Violet Stains on	719
Lime Process of Purification	633	Chromium Colours on	115
Limits of Explosibility with Air	488	Cold Scouring and Dyeing	591
Poisoning by	608	Colours Fixed by Ammonia (illus.)	53
Purification	273	Dyeing Black on	507
Purifying	393	Effect of Operations on Strength of	310
Referts	209	Sized, Treatment of	585
Washing and Purifying	209	Singeing	510
Coal-tar, Benzoic Acid in	333	Turkey-red and Alizarin on	18
Colours, History of	427	Waste, Treatment of	586
Creosote	531	Wool, etc., Treatment of (illus.)	492
High Boiling Phenols in	333	And Woolen Rags and Fibres, Treatment of	295
Products at Inventions Exhibition	471	And Dried Brown	494
Quinoline from	302	Counting Acid	135
Still for	671	Cows, Maize Silage as Fodder for	539
Thiozen from	331, 739	Malt-dust as Fodder for	537
Coals, Analyses of Furnace	738	Crassulacea, Separation of Oxygen in Leaves of	604
Cobalt, Compounds of Nitrosophthol with	278	Cream of Tartar Manufacture	282
Extraction from	319, 465	Creosote, History of	152
Extraction from Ores	287	Coal-tar	531
And Nickel, Alloys with Iron	122	Cresol	154
And Nickel, Malleable	221	Crucibles, etc., Magnesia	122
And Nickel Separation	370	For Steel	404
Ores, Treatment of	716	Triangles for	510
Treatment of Sulphurous Ores	120	Cumidine, a New	739
Cocaine, Commercial	552	Pseudo	278
Constitution of	509	Cumylquinizine Derivatives	364
Cochineal	585	Cumyl-urea	710
Cockebafers as Manure	230	Cupola Furnaces	121
Cocoa, Manufacture	415	Cypress Bark	571
Cod-liver Oil and Iron, Preparation of	687	Cypripedium	33
Corolligone	155	Cyanic Acid, Colours produced by Means of	453
Coke-dust, Utilisation	392	Cyanide Solutions, Red Colouration of	418
Coke Manufacture	669	Cyanine, Dimethyl-	339
Ovens	199, 531, 582; (illus.)	Cynol	292
Ovens, Benzene from Gases of	48		
Ovens, with collection of By-products	450	Decrustation Composition for Boilers	128
Ovens and Machinery for	450	Degutt (Distroleum Residue)	112
Ovens, Models and Drawings of, at Inventions Exhibition	470	Depeptonisation	748
Oven Tars, Investigation of	451, 452	Dephosphorising Process, Slag from	595, 596
Ovens, Treatment of Gases from	338	Desiccating Machines	47
Ovens, Treatment of Tars from	337	Desubacterium (Element for Indigo)	117
Reducing Action on Nitric Acid	41	Detonating Signals for Railways	417
Treatment of	48	Detonators	754
Water Filtered through	703	Dextrin, Estimation of	355
Coking by Means of Steam (illus.)	336	Dextrose, Circular Polarisation of	132
Oven	109	Diamidodiphenylmethane	581
Process, The Jamieson	214	Dinstar, Action of Phosphoric Acid on	399
Cold, Production of	392	Action of, on Starch	682
Colour formed in Dye-bath	455	Diazamidocumene	397
Reaction of some Diketones	370	Diazobenzenenitrile	710
Colouring Stone, etc.	335	Diazo-compounds, Action on Beta-Naphthylamine	326
Colours from Ailine Waste Liquors	111	Action of Alcohol on	275
Fixed on Cotton by Ammonia (illus.)	53	Dibromacetic Acid	63
Fixed and Produced by Electricity	306, 310	Dichlorine	416
Use of Poisonous	189	Dicumylthiourea	740
Preservation of Moist	289	Dicumylurea	740
Containing Sulphur, Manufacture of (illus.)	275	Digallie Acid, Constitution of	537
Technology of Mineral	671	Digestion, Theory of	718
From p-Toluidine	397	Diketones, Colour Reaction of Some	370

	PAGE		PAGE
Dimethylamidoazobenzene as an Indicator	330	Evaporating Apparatus	48
Dimethylamidoazobenzene Acid	394	Fumigation	582
Dimethylamine Derivatives	339	Evaporation of Liquids (illus.)	211
Dimethylcyanine	339	By means of Vacuum (illus.)	530
Dimethylxyloquinine (Antipyrine)	60	For Sugar Juice	718
Dinitrotoluene, Nitrotrilindines from	114	Excreta, Treatment of	403
Dinitroxylenes, Isomeric	339	Treatment of Human	232
Diorescin (an Explosive)	339	Disposal of	232
Diphenol, Hexamethyl-	331	Exhausting and Compressing Apparatus (illus.)	757
Diphenyl Bromine Derivatives of	662	Exhauster for Vacuum Pan	682
Diphenylamine as Reagents for Chlorine, Nitrates, and Nitrites	613	Exhibition, Apparatus and Chemicals at Inventions	469
Diphenylidocacchioride	113	International Inventions	518, 569
Dipseudoacetyl	331	Explosion, Velocity of	487
Diquinazine Blue	342	Explosions caused by Dust	487
Discharge on Vat-blue, Red	342	Explosives (illus.)	396
Discharges on Indigo-dyed Fibre	21	Explosives	417, 418, 509, 510, 573
Disinfectant	134, 210, 415, 463, 518, 517	Manufacture of	753
Disinfectants, etc., at Inventions Exhibition	567	Manufacture (illus.)	136
Disinfecting Rags, etc.	363	In Mines, Employment of	678
Soap	717	Extracts, Testing Pharmaceutical	687
Disintegrator for Semi-fluid Substances	197	Fat Estimated in Palm Meal	511
Disintegrators for Grains (illus.)	358	Estimation of, in Mineral Oils	716
Dissociation of Gases by Heat	621	Extracted from Bones, etc.	459
Distillation, Fractional	113, 511	Extraction from Bones	406
By Means of Steam, Fractional	335	From Fruit of Myristica Surinamensis	716
Under Reduced Pressure, Fractional (illus.)	612	Manufacture of Emulsions	504
Distilleries, Pollution of Rivers by	725	In Milk, Determination of (illus.)	136
Distiller's Wash, Fodder from	362	Purification of	407
Distilling Apparatus	165	Fats, Estimation of (Glycerol in	635
Apparatus, Portable	133	Examination of (illus.)	335
Dithionyl	113	Extraction of (illus.)	352
Dithioetraphenylurea	673	Preparing Emulsions of	602
Ditolyl Bromine Derivatives of	669	Purification of	679
Docks, Nitrogen in Mud from	232	Preserved by Salicylic Acid	620
Documents, Security of	318	Saponification by Steam (illus.)	353
Boundake Bark	370	Fatty Matter from Bones	257
Drying Arrangement for Mud, etc.	196	Matter Extracted from Sewage	461
In Vacuo	392	Substances Distilled by Superheated Steam	717
Dung Substitute, Algin as a	519	Ferment free from Bacteria	506
Durene, Formation of	270	Which does not Invert Raw Sugar	513
"Duresco," a Substitute for White Lead	345	Fermenting Vat for Wine (illus.)	237
Duric Acid	278	Warts, Influence of Phosphates on	376
Dust, Explosions caused by	186, 487	Ferric Oxide, Action on Sulphates	281
Dye-bath, Formation of Colour in	453	Ferro-chromium Alloys	678
Dyeing	155	Ferrocyanides from Gas-liquor	113
Fabrics Unstretched (illus.)	240	Ferro-nickel Alloys, Malleable	122
Fibre	333	Fibre, Neutralising Acid in (illus.)	492
Antimony Compounds used in	613	From Wood	586, 713
Cotton	501	Fibres, Treatment of	586, 713
Garments, etc.	281	New Material from	731
Preliminary Treatment for	115	Filter Presses	101, 105, 331, 332, 530, 736
Straw	587	Paper, Toughened	211
Wool, etc.	604	Press for Laboratory Use	612
Dyes, etc., made by the Badische Anilin- und Soda-Fabrik	480	Pressed Sewage Sludge	192
Yellow Azo	338	Separating Sludge	196
Dyewoods, Colours from	518	Filters	105, 131, 195, 668, 686, 736
Dyewood Extracts	433	Asbestos Membrane for	530
Extract, Testing	206	For Beet Juice (illus.)	233, 231
Dye-works, Classification of Waste Waters from	608	For Water	433
Pollution of Rivers by	730	Filtering Apparatus	431
Dynamite Cannon (illus.)	213	Machine	47
Determination of Nitroglycerine in (illus.)	136	Medium	237
Removal of Erections by (illus.)	361	Fire-damp, Effect of Shot-firing on	186
Earthenware, etc., at Inventions Exhibition	500	Fire-lighters	303
Manufacture (illus.)	317	Fireproof Composition	211, 212
Education, Scientific and Technical	650	Fireproofing Composition from Slag, etc.	586
Ehrmannite (a Crystalline Superphosphate)	566	Fire Workshops	71
Elastine (Artificial Indiarubber)	289	Fish, Manuring with	127
Elasticity of Iron and Steel	609	Preserving Smoked	685
Electric Lamps, Catalogue	608, 685	Roast, Treatment of	685
Light, Influence on Plants	231	Flame, Furnaces Heated by (illus.)	439
Lighting, Prospects of	388	Flame, Furnaces Heated by Radiant Heat of	332
Electrical Conductors, Alloys for	507	Flavaniline	277
Electricity, Colours fixed by	306	Flavenol, Oxidation of	277
Smelting Ores by	517	Flooring, Metallic	679
Electrodes for Secondary Batteries	517	Flue-dust, Collection and Treatment of	351
Electrogen, an Anticorrosive for Boilers	48	Furnace Gases Cleaned from (illus.)	217
Electrolysis, Decomposition of Haloid Salts by Sulpho-colours produced by	461	Fluorine	273
Electrolytic Bleaching (illus.)	153	Nitro	273
Deposition of Metals	673	Detection and Estimation	759
Discharge of Indigo and Turkey Red (illus.)	731	Flux for the Thomas Process of Iron Working	679
Extraction of Copper	600, 601	Fodder from Distiller's Wash	428
Manufacture of Chlorine	214	Food, Algin as an Article of	519
Process for Chloroform, etc.	213	Preserved	292
Recovery of Tin from Scrap	312	Preserving	362
Electro-plating Chromium Alloys	331	Value of Bran as	129
Elevator for use in Sugar Making	292	Frost, Potatoes Damaged by	237
Emeraldine (Aniline Black)	206	Fuchsin in Wine	291
Emulsions of Fats and Oils	501	Fuel, Artificial	111, 201
Enamel for Metals	596	Calorimeter for	332
Enamelled Vessels, Lead in	515	For Blast Furnaces	216
Enamelling, etc.	716	Machine for Artificial (illus.)	197
Ensilage, Cellulose	132	Fumigating Compound	517
Preserving Green Crops for	130	Fume, Filtration without Access of Air (illus.)	368, 369
Eosine	434	Hot-water (illus.)	291
Erythrol, Thiophen from	335	Furnace, Apparatus and Apparatus for Burning Liquid Hydrocarbons	48
Ethane, Illuminating Power of	267	Furnace, Carbonating or Calcining	322
Eucalyptol	292	For Chemical Operations	175
Euphorbia Paints	290	For Extraction of Copper	515
Eupitonic Acid	156	Gases, Benzene from	531
		Gases, Liquid Sulphurous Acid from	671

	PAGE		PAGE
Furnace Gases, Sulphur from	487	Gelatine Process of Water Examination (illus.)	628
Gases, Utilization of (illus.)	217	Generator Gas, Analyses of	321
Gases, Utilization of	737	Genessee Oil	35
Lead Smelting (illus.)	51	Germination, Influence of Mineral Substances on	128
For Recovery of Soda (illus.)	116	Gilding Pottery	211
Regenerative	601	Glasgow Section, Chairman's Address to	650
For Salt Cake, The St. Beke	316	Glass, Action of Acids on	215
For Shale, etc.	337	Action of Liquid Carbonic Acid on	103
For Small Coal	111	Etc., Coated with Aluminium	225
Smelting	223, 503	Enamelled	53, 51
Tar, Examination of	738	Furnace Heated by Flame	143
Furnaces, Basic Linings for	221	Imitation Stained	283
Blast, Cold and Regenerative	12	Exhibitions Exhibition	560
For Blende (illus.)	51	Manufacture	53
For Hydrocarbons	201	Manufacture of Milk	103
For Burning Hydrocarbons	582	Manufacture of White Opaque	319
For Burning Petroleum Residues (illus.)	78	Mixings for	36.0
Carbonating or Calcining (illus.)	535	Moulding Machine for	675
Heated by Flame (illus.)	139	Opal	362
Heated by Radiant Heat of Flame	352	Silvered	53
Heated by Radiation from Flame	620	Solubility of	349
For Gas	110	Toughened	335
At Inventions Exhibition	170	Glover Tower Lined with Ordinary Red Bricks	33
Puddling	221	Glycerine, Manufacture of	537
For Roasting or Calcining	212	Manufacture of, from Indian Corn	683
Tar and Ammonia from	737	From Wood	507, 551
Fuses, Combustible Composition for	753	Glucosides, Colouring Matters from	507
For Shells	117	Glucose-vanilla	505
Galactose	412	Glycerine, Boiling Point and Specific Gravity of	226
Gallein, Constitution of	672	Estimation of	610
Galls, Tannin in	261	Extraction	288
Galvanizing Works, Refuse Liquors of	725	Purifying	198
Gambler, Tannin Destroyed by Boiling Solution of	266	In Wine	292
Gas, Analyses of Natural and Producer	152	Glycerin, Sweetness of	36.0
Analysis (illus.)	265	Gold Amalgamating	120, 221, 678
Analysis Apparatus (illus.)	180	Mercurial Stains Removed from	351, 332, 401
Analysis, Hempel's Methods of (illus.)	160	In the North of Japan	595
Apparatus for Correcting Volume of (illus.)	757	Silver Coated with	596
Prova Borings at Middlesbrough	650	And Silver Extraction	716
Burners, Argand	250	Working Ores Containing	503
Burners, Christiansen	250	Gossow	288
Burners, Air Compressor for	110	Grains, Drying Brewer's	411
Carburetted	669	Grape Stones, Influence on Red Wine	358
Coal, Analysis of	656	Stone Oil	412
From Coal Dust, etc.	333	Sugar in Brewing	353
Collecting, for Analysis	698	Sugar Estimation	542
Composition of Natural	708	Graves, Extraction of Colour from	355
Engine, Worked with Carburetted	737	Grease, Manufacture of Lubricating	602
Extraction Tube for Bone-black Retort (illus.)	682	Recovery from Fibres, etc.	226
Fuel, Natural	152	Recovered from Soap Water	288
Furnace (illus.)	441	Green, Guignet's	302
Furnaces	110	Grids for Purifying	592
Furnaces Heated by Flame	630	Guaiacum Resin, Products of	153
Generators	200	Guano from Fish Refuse	565
Heated Kilns	535	Gun in Wood, Formation of	541
For Heating	392	Gums, Absorption of Bromine by	96
From Hydrocarbons	201, 268, 150	Gunpowder	751
Indicator for use in Mines	716	Manufacture	753
Laboratory Apparatus for Continuous Production	689	Presses for	569
(illus.)	689	Smokeless	573
Lighter for	609	Gut, Substitute for	451
Lime, Revivification of	582	Gutta-serena (Substitute for Gutta-percha)	570
Liquor, Pollution of Rivers by	750	Gypsum, Sulphuric Acid from	210
Liquor, Utilization of (illus.)	112		
Manufacture	199, 204, 581	Hæmoglobin in Blood, Determination of	511
Manufacture of Carburetted (illus.)	106, 111	Halogens, Estimation (illus.)	689
Manufacture from Hydrocarbons	308	Influence of Light on Reactions of	398
In Mines, Collecting	199	Haloxylon (an Explosive)	366
Oil	109	Hanks, Colours printed on	155
From Oil Wells, Employment of	39	Hay, Comparative Values of	537
Producers	201, 332, 303, 440 (illus.)	Composition of Unwholesome	407
Producer and Steam Boiler Combined	200	Iazoline (A Scent for Soap)	565
Producers, Analyses of Gas from	173	Hellhoffite (an Explosive)	136
Producers, Carbonic Oxide obtained from	737	Hellin	505
Purifier Grids	200	Herbage, Composition of	8
Purification	185	Heterodora (Beet-hemuloids)	538
Purifying (illus.)	107, 108, 109, 110	Hexamethyl-violet	156
Referes' Table, Extended	690	Hexamethoxylaurin	156
Retort, Experimental	659	Hides, Treatment of	717
Retorts, Ascension Pipes of (illus.)	107, 110	Homomorphous, Synthesis	593
Retorts with Glazed Lining	18	Honey, Analysis	355
Retorts, Mouthpiece for	582	Composition and Administration	411
Retorts, Regenerative System of Heating	582	Hop Liqueur	362
Scrubber	268	Substitute	123
Self-igniting	737	Hops, An Acid in	513
Separation of Heating from Lighting	488	Experiments with	539
Etc., Strainer for	392	Extract of	133
From Wieliczka Mine, Analysis of	724	Choline in	204
Gases, Ammonia from (illus.)	111, 198, 337	Drying (illus.)	361
Apparatus for Making Small Quantities (illus.)	181	Influence on Keeping Properties of Beer	683
Arrangement for Washing	213	Manning	603
Benzene from Coke Oven	188	Treatment of (illus.)	550, 361
Combustion in Dried	582	Value of, in Keeping Beer	565
From Coke Ovens	668	Horse-chestnuts, Analyses of	538
Combustion of Dry	569	Hungary, Sugar Cane Cultivated in	461
Compressed	197	Hydrargyri Unguentum and Pilula, Preparation of	25
Compressor for	612	Hydrargyrum cum Creta, Preparation of	782
Brought for Poisonous, in Laboratories	612	Hydrargyric Malt, Gas	582
See Furnace Gas		Hydrobromic Acid, Manufacture	576
Pumps for Compressing	105	Hydrocarbon Furnaces	201
Tar and Ammonia from Blast Furnace	531	Gas	201
Various Modes of Treating Liquids with	639	Vapour for Gas Engines	581
Gay-Lussac Tower, Reduction of Nitric Acid in	31	Hydrocarbons, Furnaces for Burning	582

	PAGE		PAGE
Hydrocarbons, Furnace and Apparatus for Burning Liquid	48	Iron, Sponge, Manufacture of	679
Gas from	268, 450, 531	Spongy	133, 351, 363
Methyl eliminated from	270	Stone, Extraction of Iron from	221
Peat employed in Treatment of	200	Sulphate from By-products of Paraffin	471
Hydrochloric Acid free from Arsenic	200	Treatment of	223
Manufacture	117, 315, 457, 458	From Sulphide or Oxide	223
Gas from its Solution	533	Treatment of	225
Occurrence of Selenium in	33	And Tungsten, Alloy of	676
In Plants	407	Variation in Elasticity of	100
Solubility of Calcium Sulphate in	34	Water treated with Spongy	703
Vapour, Effect on Vegetation	540	Working Auriferous and Argentiferous Ores	288
Apparatus for making	612	Isabonaphtha (Mineral Machine Fat)	112
Hydrogen, Combustion of	668	Isatin	203
Manufacture	150, 757	Condensation Products of	741
Peroxide, Analysis by means of	613	Italian Tartar Industry	494
Peroxide, Assay of	180	Ivory, Artificial	751
Peroxide formed by Moist Bone Black	682	Vegetable, Dust proposed as Food for Cattle	603
Peroxide, Employment of	553		
Peroxide, Manufacture and Uses of	508	Janite (an Explosive)	366
Peroxide produced by Combustion of Carbonic Oxide		Jatropha Curcas, Oil of	371
and Hydrogen	668	Jerusalem Artichokes, Alcohol from	238
Hydrotinoline	394	Juglone	292
Hydrolysis of Soap	629	Jute, Products of Distillation	377
Hydroxycinnic	293	Fibre, Constitution of	11
Hydroxylamine, Photographs Developed by	572		
Hydroxyquinoline from Cotton Cake	411	Kaeroline, Derivatives of	752
Hygienic Candles	241	Kelp-substitute from Sea-weed	518
Crystals	518	Ketone Bases, Colours from	472
Hypophosphoric Acid, Basicity of	401	Based on Hydrogen Derivatives of	591
Hyposulphurous Acid, Titanic Acid as Reagent for	736	Kieselguhr, Fireproofing Composition made from	196
		Kiln for Pottery, etc.	119
		Kilns for Bricks, Lime, etc.	283
		Gas-heated	335
		Heated by Gas	47
		Kinetic (an Explosive)	505
		Kola Paste	371
Ice Manufacture	419	Laboratory Apparatus (illus.)	294
Manufacture (illus.)	736	Laemoid, from Resorcinol	206
Incandescing Lamps of Russian and American Petroleum	70	Lacquer, Brilliant	227
Incrustation Preventive for Boilers	184	Lactic Acid Manufacture	716
Preventive	105	Lake, Turkey-red	301
Indazole Compounds	63	Lamp, Carcel, Value of	258
Indian Corn, Glucose from	683	Mineral Oil	198
Indinuber, Artificial	889	Petroleum (illus.)	387
And its Decay (illus.)	710	Standards of Light	251
Substitutes for	680	Lard, Bedding, etc.	501
Indicator, Dimethylamidoazobenzene as an	510	Lavas from Etna and Vesuvius, Analysis of	128
Resorcinol Laemoid as an	296	Lead, etc., Continuous Lengths of Sheet	122
Indicators, Alkalimetric	137, 552	Copper coated with	678
Influence of Boric Acid on	611	In Enamelled Cooking Vessels	515
Liebermann's Phenol Dyes as	584	Extraction in the United States	30
Indigo, Artificial	378, 134	Tricarbonate, Action on Sodium Pentasulphide	581
Blue, Chrome Discharge of	493	Moulds, Mineral Oils for Lubricating	227
Blue Discharged by Electrolysis (illus.)	312	Oxidation of	675
Blue, Red Discharge on	312	Pigments	123
Dyed Fibre, Discharges on	312	Pipes, Action of Water on	545
Electric Fixation of	309	Poisonous Effect on Vegetable Organisms	161
Printing	53	Produced in Germany in 1881	600
Printing with Artificial	454	Red, Treatment of	289
Valuation of	189, 191	Separation from Precious Metals	122
Yat	493	Smelting, Furnace for (illus.)	54
Indigodicarboxylic Acid	596	White	354
Indopneum	741	White (illus.)	227
Injector used for Gases from Pyrites Furnace	194	White (illus.)	363, 561
Inventions Exhibition, Apparatus and Chemicals at 1881	518, 569	Lead Pipes for Water-supply	608
Iodides, Chlorine Determined in presence of	756	Leather, Artificial	337, 747
Iodine, Chloride with Alkaloids, Compounds of	687	Adulteration of	504
Detected in Presence of Iodine	207	Black Varnish for	602
Detection and Estimation	211	Chrome-tanning	365
Estimation of	214	Glazed	747
Mixed with Paraffin for Candles or Ointment	680	Manufacture	229
Iodoform	569	As Manure	232
Manufacture	213	Meal as Manure for Oats	127
Iridium, Extraction of	405	Waste, Nitrogen in	538
Iron, Alteration of Constituents of Cast	677	Leatherette	747
Analysis	690	Leaves, Amylase present in	460
Blast Furnace, Working of	677	Value of Freshly-fallen	408
Carbon in	281	Lederite (an Explosive)	137, 366
Coated with Copper	593	Legumin, Behaviour with Solution of Salt	231
Chloriometric Determination of	613	Leguminosae, Absorption of Nitrogen by	601
Combination with Carbon	231	Lepidine Carboxylic Acid	277
Conversion into Steel	122	Leucine in Beet-root Molasses	539
Distinguished from Steel	138	Light, Influence on Germination of Seeds	110
Employed in Voltaic Batteries (illus.)	728	Influence on Reactions	398
Etc., Enamelling	716	Standards of	250
Extraction of Titanium in	419	Lignite (an Explosive)	366
Extraction from Ironstone	224	Mineral in Filtering Medium	237, 240
Influence on Silicon on Properties of Cast	745	Mined in France in 1881	582
Influence of Silicon on Properties of	677	Lignocellulose, Treatment for Paper Pulp	11
Malleable	223	Lime Acetate, Valuation of	497
And Manganese Alloy	287	Chloride, Valuation of	687
Manganese and Phosphorus Determined in	137	Influence on Germination	128
Manufacture	287	Prepared for Land	253
Manufacture, Flux for Thomas Process	679	Phosphate, Manuring Experiments with	109
Mordants in Silk Dyeing	207	Process of Clarifying Beet-juce	541
Nitrosophthalol Compounds with	278	Process of Purification of Coal Gas	633
Ores, Purification of	351	Reactions with Sulphur	634
Ores, Reduction of	352, 678	Removed from Phosphatic Minerals	117
Ores, Titration	419	Revivification of Spent	582
Ores, Treatment of Dusty	352	Salts, Influence of, on Nitrification	460
Paint for Protecting	227, 459	Salts in Plants	511
Precipitation of Copper by means of (illus.)	728		
Precipitation of with Cod-liver Oil	687		
Protecting Submerged	601		
Purification of	601		
Purification of Water by (illus.)	511		
Silicon Determined in	157		

	PAGE		PAGE
Lime, Steam Generated by Slacking	430	Melting Pot for Metals	120
Sulphate for Paper-making	610	Menthhol	571
Superphosphate	290	Mercurial Stains removed from Gold	395
Liht. Substitute for	493	Mercury Compounds, Preparation of Medicinal	235
Liquids, Concentration of, by Hot Air	520	Metadiamidomethoxylene	203
Sampler for	511	Metallurgical Industries of the United States	26
Various Modes of Treatment with Gases	639	Metallurgy, Progress in (illus.)	319
Liquoree Root in Brewing	283	Metals, Action of Chlorates on	32
Lithographic Stones, Artificial	483	From Chlorates by Electrolysis	275
Lixivation Apparatus (illus.)	331	Co-operation of Water in Oxidation of	67
Logwood Extracts	585	Electrolytic Deposition of	751
Lubricating Compound	288	Enamel for	596
Metal Moulds	227	Extracted from Cinders, etc.	223
Oils from Petroleum Residues (illus.)	111	Influence of some, on Mixture of Acetylene and Air	668
Oils Testing Mineral	501	Melting Pot for	166
Oils, Viscosities of	77	Oxygen in	477
Lupine, Alkaloids in	588, 602	Metanidocresol, Colours from	399
Nourishment in	108	Metanitroxylidine	203.
Removal of Bitterness from	407, 408	Metaxylene, Nitro and Amido Derivatives of	399
Treated for Cattle Food	461	Metaxylidiaz, Nitration in Presence of Sulphuric Acid	399
Lutidine (Alpica)	794	Methacrylic Acid	198
Synthetic	336	Methan Illuminating Power of	198
A Third	488	Methoxynicotinic Acid	135
Madder, Revival of Natural	19	Methyl eliminated from Hydrocarbons	270
Magnesia	429	Alcohol, Estimation of	267
Wine Colored with	543	Orange, as Indicator	157
Magnesia Crucibles, etc.	122	Violet Crystallized	265
Process of Clarifying Sugar	511	Violet Sulphonic Acid	111
Salts, Influence of, on Nitrication	460	Methylene Blue	276, 277
Magnesium and its Alloys, Depositing	352	Methylhydroquinoline, Derivatives of	752
For Bengal Lights	689	Microbes in Filters of Sugar Refineries	606
Chloride, Chlorine from	498, 513	Milk, Condensed	367
Carbonate, Solution by Carbonic Acid	314	Deterioration of Fat in (illus.)	662
Decomposition of Chloride, etc. (illus.)	456	Emulsions of Fat mixed with	602
Lime Saccharate	357	Formation of	129
Oxychloride as a Bleach	205	Influence of Cotton Cake on	127, 129
Oxychloride, Chlorine from	17	Influence of Malt Dust on Yield of	357
Oxychloride, Decomposition of	457	Peptonised	238
And Potassium Bicarbonates of	496	Preservation	543
Maize, Experiments on Growth of	127, 130	Sugar	412
Manufacture of Starch from	718	Sugar, Detection of Cane Sugar in	718
Etc., Oil Extracted from	439	Milk Glass, Manufacture of	403
A Product from	132	Mill for Phosphates, etc.	272
Slage as Fodder for Cows	529	Mine, Gas from Wietleszka	721
Treated for Manufacture of Spirits	685	Mineral Oils, Soap containing	123
Malachite Green	203	Miaes, Collecting Explosive Gas in	199
Malt	506	Employment of Explosives in	678
Analyses of	377	Mining Department at Inventions Exhibition	561
Dust as Fodder for Cows	537	Mixer for Fluids and Semi-fluids	407
Nitrogen in	513	Molasses, Refinose from	187
Preparation of	238	Sugar from	355, 356, 357
Production of	133	Sugar extracted from	461
Treatment of Amylaceous Substances with	237	Sugar of High Rotating Power from	290
Malted Food Preparations	567	Mononitrophenol	398
Maltng	412	Montague, Steam Trap for (illus.)	234
Malto-dextrin	683	Mordant, Algin as a	310
Maltose	412	Chrome	812
Manganese Copper	287	Titanic Acid as a	310
Determination	510, 690	Mordants, Antimony Compounds as	313
Determined in Iron	157	Chemistry of	586, 588, 590
Estimation in Spiegeleisen, etc.	119	And Colouring Matters from Glucosides	207
Extraction of	319	Effect of Strength of Cotton	310
Extraction from Ores	287	Ferrocyanides as	812
Oxide, Recovery of	498	Mould for Artificial Fuel (illus.)	197
Peroxoide, Analysis of	613	Mucic Acid, Thiophen from	269
In Plants	538	Must, Sugar and Acids in	362
And Potassium Cyanides	401	Myline (an Explosive)	366
Precipitation by Iodine	367	Myricic Acid, Source of	716
"Manipulator" for Refining Iron	257	Myrogene for Extracting Perfume from Flowers (illus.)	572
Manitoba Soils, Sources of Fertility of	601	Naphtha, etc., Condenser for (illus.)	196
Manure, Cockschaifers as	230	Valuation of	719
For Hops	603	Wood	318
Leather shavings as	232	Purification of Wood	730
Manufacture	680	Naphthas, Valuation of	615
Loss of Nitrogen from Farnyard	460	Naphthase	276
Peat as a	409	Naphthol from Coal Tar	333
Sulphuric Acid as a	126	Colours at Inventions Exhibition	176, 477
Superphosphate of Ammonia as a	126	Green	204
Manures	123	Carbonates	331
Artificial, at Inventions Exhibition	565, 566	Naphtholazobenzene, Derivatives of	278
Artificial, in the United States	29	Naphtholdisulphonic Acids	339
For Beet	355	Naphtholquinoxalinesulphonic Acid	291
Experiments with	126, 127, 130	Naphthols, Azo Colours from	152, 453
Nitrogen Determination in (illus.)	121	Nitros	338
For Vines	559	Naphtholsulphonic Acids, Manufacture of	50
Manurial Experiments	539	Separation of	400, 452
Value of Peat Waste	108	Naphthylamine (beta-), Action of Diazo-compounds on	395
Value of Pressed Sewage Sludge	12	Compounds	202
Value of Sewage	230	Derivatives	278
Manuring Experiments with Phosphate of Lime	460	(beta-) Sulphonic Acids	339
Marble, Artificial	215, 216	Naphthylsulphonic Acid (beta-), Colours from	712
Stone, etc., coloured	535	Narcene, Derivatives	508
Marbled Glass	53	Natural Agencies, Water Purified by	705
Markkohl as a Fodder, Value of	126	Nettles, Treatment of Fibres from	713
Markkols, Manufacture	417, 418	Nickel, Alloys containing	229
Match-making Machinery (illus.)	26	Borates, Crucibles, etc.	119
Materials for Acid Works, Cost in the United States	28	And Cobalt, Malleable	221
Mauveine	428	And Cobalt, Separation	370
Meat Extracts, Preservation of	462	Extraction of	165
Preserving	239, 415	Extraction from Ores	287
Powder Manufacture	292	Ores, Treatment of	121, 716
Meeting, Proceedings of Fourth Annual	426	Treatment of Resinical Ores	190
Megass, Sugar from	291	Nicotine, Reactions of	68

Residues, Lubricating Oils from (illus.)	111	"Poussiere," Analysis of	138
In Russia (illus.)	70, 111	Powder, Blasting	117, 418
Treatment of	333, 679	Prairie Soils, Composition of	604
Phenanthrenequinone as a Re-agent for Aromatic Ortho-	311	Precious Metals, Separation of Lead from	122
diamines	614	Precipitation Process of Sugar Making	355
Phenol as Re-agent for Nitrates and Nitrites	581	Preserving Fabrics	205
Dyes, Lieberman's	581	Priming Composition	289
Phenols, Colours, Dioxo-derivatives of	400	Printing, Antimony Compounds used in	643
In Blast Furnace Tar	738	Blue Grounds	493
In Coal Tar	333	Machine for "Calico"	673
Colouring Matter from	576	Producer Gas, Composition of	267
Conversion into Amines	276	Propane, Illuminating Power of	312
Phenolphthalein as Indicator	137	Prussiates, Fixing Colours by Means of	338
Phenolsulphonic Acid, Dinitro-	203	Pseudocumene Derivatives	338
Pheno-nuaveine	128	Pseudo-cumol	333
Phenylhydrazine, Action of Diacetosuccinic Ether on	61	Pseudo-cumidine	278
As Discharge on Heat	267	Derivative of	307, 189, 339
Phenylazine acetosuccinic Ether	61	Pseudo-nuaveine	428
Phenylsulphocarbazine	63	Puddling Furnaces	224
Phlorone	741	Pulp Manufacture	135
Phloxine	431	Pumps, Cleaning Beer	153
Phosgene, Colours produced by	432	For Compressing Gases	105
Goa, Purple Colours from Action of	101	Purity of Effluent Water, Standards of	85, 48
Phosphate of Lime, Manufacture	173	Purple Colours from Action of Phosgene Gas	421
Phosphates of Alumina and Lime	497	Putrefaction Germs in Cattle Foods	461
Alkaline	671	Pyrenequinone Dioxo-	488
From Basic Slags	535	Pyridine Derivatives	135
Influence on Fermenting Worts	576	Pyridine Acid	398
Manufacture	121, 229, 408	Pyruvic Acid	394
Manufacture of Alkaline	211	Series, Colours from Chloridic Bases of	433
Manufacture and Treatment	355	Tetracarboxylic Acid	277
Etc., Mill for	232	Pyrites Free from Arsenic	533
From Slags	226	Composition of Gas from Combustion of	457
For Sugar Beet and Barley	539	Estimation of Sulphur in	329, 419, 573, 671
Treatment of	459	Explosives	191
Treatment of "Redonda"	131	Furnace, Blower used for Gases	497
Phosphatic Substances, Treatment for Manure	117, 391	Sulphur from	497
Minerals, Treatment of	341	Pyroaceticin	154
Phosphoric Acid, Crystallised Hydrate of	290, 552	Pyrometer, Water (illus.)	194
Determination	296	Pyrometers	194
Determined in Superphosphates	211	Pyrometers (illus.)	281
Estimation of	127	Pyrosulphates	259, 739
Estimation of Reduced	571, 576	Pyroline Derivatives, Synthesis	61
Manufacture (illus.)	338	Quinine	126
Reversion of	419	Quinine Alkaloids	64
In Sewage Sludge	377	Chloride	756
In Stones and Soil, Assimilability of	576	Commercial Sulphate of	551
In Worts	108	Determination of Cinchonidine in	293
Phosphorus Acid Oxidised by Bromine	137, 680	Hom., Synthesis	116
Phosphorus in Coal and Cannel	572	Sulphate, Commercial	352
Determined in Iron	146	Vogel's Test for	60
Photographic Sensitive Paper	250	Quinazone Derivatives, Constitution of	688
Photographs developed by Hydroxylamine	188	Quinoline Bases, Reactions of	436
Photometer (illus.)	39	Compounds	461
Radiation	277	Disulphonic Acids	740
Photometric Value of Ethane and Propane	76	Dimethyl-	302
Value of Methane	277	Homologues of	355
Values of Petroleum and Kerosene	753	Series, Colours from Chloridic Bases of	433
Phthalic Acid, Beta-Sulpho-	25	Tetrahydro-	63, 361
Picoline-tricarboxylic Acid	571	Trimethyl-	291
Picrates, Explosives containing	162	Quinoline Acid	381
Pilula Hydragryi, Preparation of	132	Quinones from Paramethylated Amines	388, 489
Pice Extract	410	Radiation of Heat	622
Pictettes (gas filter)	408	Raffinose (a Sugar from Molasses)	290, 111, 505
Pittsburg, History of	107	From Molasses of Beet	607
Plants, Absorption of Nitrogen by	241	Ragazine Oil	77
Effect of Zinc Salts on	338	Railway Signals, Red Paint for	337
Hydrochloric Acid in	118	Rain Water, Constituents of	403
Influence of Electric Light on	559	Reflectors, Experiments with (illus.)	475
Manganese in	405	Refrigerating Apparatus at Inventions Exhibition	633, 679
Plastic Compound	189	Resia, Distillation of	328
Platinum Ores, Analysis of	531	Resorption of Bromides by	96
Production in Russia	721	Resorcinol, Amido-	52
Poisonous Colours, Restrictions against Use of	2	Azo-	50
Poisons, Detection of	139, 166	Dibromoazo-	51
Pollution of Rivers	345	Laenoid from	230
Pollution of Rivers by Chemical Works	308	Tetrazo-	51
Of Rivers, The Proposed Bill on	214, 395	Trinitroazo-	51
Standards of	117	Hexanitroazo-	51
Of Thames in 1881	212	Retene	391, 629
Ponceau Identification of Benzidine	460	Retistene-quinone	391
Potash Bichromate	671	Retort for Bone Black with Gas Extraction Tube	682
Carbonate and Bicarbonate	713	For Extraction of Bitumen (illus.)	185
Chlorate			
Salts, Influence of, on Nitration			
Potassium Carboxide, Benzene Derivatives from			
Chlorate, Action of Heat on			

	PAGE		PAGE
Retort and Still for Nitrogenous Substances (illus.)	670	Silk-dyeing, Iron Mordants in	207
Retorts for Animal Charcoal	199	Silicates, Manufacture of Alkaline	211
Apparatus for Charging	114	Silos	290
Gas, with Glazed Lining	269	Covers for	130
Self-acting	199	Silver, Amalgamation of	678
Self-sealing Mouthpieces for	201	Coated with Gold	746
Rhea Rammie Fibre	332	Extracted from Antimony Ores	332
Rhexite (an Explosive)	360	Extraction of	401
River Mud, Nitrogen from	232	And Gold Extraction	503
Thames, Pollution of, during 1884	515	Oxide, Action on Sodium-pentasilphide	281
Water, Pollution of, by Works	719	Produced in Germany in 1884	600
Rivers Pollution Bill	157, 165	Separation of	225
Pollution Bill, The proposed	2	Working Ores containing	288
Pollution Bill, Discussion	93, 98	Silvered Glass	53
Roasting, Constitution of	478	Singapore, Temperature of	115
Rockets for Throwing Oil	754	Machines for Fabrics	125
Roots, Action of, on Minerals	110	Sizing, Washing, etc., of Yarn	280
Formation of Sugar in	232	Slag, Artificial Manure from	131
Rosaniline, Blues from	398	Bricks, etc., from	283
Derivatives	279	Fireproofing Composition made from	536
Dyes, Preparation of	188	Treatment of	439
Hexamethyl-	395	Treatment of Phosphatic	595, 596
Hexmethoxypara-	136	Wool employed in Manufacture of Artificial Stone	216
Series, Coloured Derivatives of	201, 205	Slags, Phosphates from	535
Series, Violet and Blue Colours of	100	Treatment of Basic	106
Theory of Formation	385	Treatment of Phosphatic	235
Rosin Oil for Paints, Varnish, etc.	288	Smelting Furnace	323
Rosolic Acid	131	Soap Analysis	369
Rosophenylene	475	Chemistry of	625
Rotation of Crops, Experiments on	129	Containing Mineral Oils	123
Rubber Composition	288	Curd	354
Ruby Glass Wedge for Estimation of Hemoglobin	511	Detergent	747
		Disinfecting	717
		Hard	226
		With Juice of Wych Hazel incorporated	159
Saccharin, Reactions of	607	Manufacture	288, 406, 407, 602
Saccharine (a Toluene Derivative)	608	Resin	227
Saccharine Liquors, Strontia Treatment of	132	Sunphire	608
Saccharogen	129	Waxes, Extracting Grease from	288
Saccharose, Inverted Sugar from	291	Soaps, Chemical Action of	601
Saffranine Derivatives of <i>o</i> -Toluylenediamine	397	Etc., at Inventions Exhibition	562
Saffranines	129	Petroleum Derivatives used in	679
Sulcyl-aldoxim	505	Soda, Ammonia Process	157, 158, 526, 527, 595
Sulphuric Acid	361	Ammonia Process (illus.)	508
Manufacture	135, 351	Bichromate	282, 521, 591
For Preservation of Fats	680	Bichromate	117, 282
Synthesis of	688	Bisulphate, Treatment of	213
Salt Borings, Composition of Gas from	650	Carbonate, Manufacture	315
Salt-cake Furnace	316	Chromate	591
Salt, Large-grained	198	Chromate and Bichromate	211, 213, 214
Manufacture	282, 158	Cooling, Fused Caustic (illus.)	446
Manufacture from Brine	674	Crystall Carbonate	523
Removing Impurities from	313	Etc., Furnaces for	212
Treatment of	674	Granular Carbonate of	497
Salts, Decomposition by Water	101	Ley, Testing for Impurities in	687
Solubility of	101	Manufacture	117, 211, 212, 533, 595
Solubility of Mixed	592	Manufacture in the United States	711
Sampling-tube for Liquids	511	Nitrate, Method of obtaining (illus.)	495
Santonin from Artemisia Gallica	610	Packages for Caustic	498
Santonine	213	Recovered from Liquors (illus.)	116
Industry of Turkestan	135	Salts, Influence of, on Nitrification	460
Saponification by Steam (illus.)	353	Sulphate	592
Schools, Science in	81	Sulphate	147
Scouring Machine	712	Waste, Recovery of Sulphur from	209
Scrubber for Coal-gas	268	Waste, Sulphur Recovery from (illus.)	144, 173
For Gas (illus.)	108, 110	Sodium and Aluminium Fluoride	741
Seaweed, Treatment of	518	Chloride, Solubility of Calcium Sulphate in Solutions of	31
Useful Products from	394	Hypochlorite	593
Seeds, Influence of Light on Germination of	410	Manufacture	224
Oil extracted from	501	Pentasilphide, Action of Lead Hydrate and Silver	281
Oil extracted from (illus.)	352	Oxide on	281
Selenium, Occurrence in Hydrochloric Acid	33	Phosphide employed for rendering Gas Self-igniting	737
Senecio Oil	35	Sulphate, Action on Ammonium Sulphate	543
Senecio-leaves, Active Principle in	116	Soil, Assimilability of Phosphoric Acid in	110
Senecio-euclid, Active Principle in	538	Soil, Biotic Region, Constitution of	602
Sewage, Automatic Treatment of	362	Hydration of	680
Decolorisation of	163, 161	Solution, Law of	341
Fatty Matter extracted from	161	Spectroscopic Determination of Permanganate Solutions	510
Irrigation	459	Spiegelstein, Estimation of Manganese in	419
Manurial Value of	230	Spirit Distilleries, Apparatus for (illus.)	358
Mud, Drying Machine for	220	Spirits, Manufacture of	412
Sludge, Value of	302	Treatment of Maize for Manufacture of	685
Sludge, Value of Pressed	12	Treatment of New	115
Treatment of	134, 232, 239, 240, 546, 603, 686	Splint Coals, Analyses of	738
Utilisation of	355	Springs containing Carbonic Acid	743
Value of	538	Standards, Photometric	494
Shale, Black Petroleum from	536	Starch Chloride	494
Composition of	337	Starch	236, 237
Etc., Distillation of	337	Action of Diastase on	682
Distillation	274	Coloured and Gloss	237
Products at Inventions Exhibition	472	Explosive containing	753
Shells, Absorption of Bromine by	97	Manufacture	542
Align	123, 124	Manufacture (illus.)	536
Ships Bottoms, Anti-fouling Paint for	286	Meal Manufacture	718
Sheathing for	368	Moisture in	511
Silicates, Fusion Reagent for	121	As Substitute for China Clay in Printing	493
Manufacture of Alkaline	741	Sugar Syrup, Composition of	411
Treatment of Alkaline	363	Starchy Substances, Treatment with Malt	207
Silico-carbon for Batteries, etc.	222	Steam Boiler and Gas-producer combined	200
Silicon Bronze	137	Boilers, etc., Composition for Coating	668
Determined in Iron and Steel	677	Fractional Distillation by	335
Influence on Cast-iron	715	Generated by Slaking Lime	450
Influence on Properties of Cast-iron	591	Superheated, for Coking, etc. (illus.)	536
Silk-dyeing with Azo-colours			

	PAGE		PAGE
Steam Trap for Montejus (illus.)	234	Suppl. ur. from Sulphuretted Hydrogen	117, 158
Tubes for Liquor Boiler (illus.)	682	Volumetric Determination of	613
Worm for Vacuum Pan	682	Sulphuretted Hydrogen, Arsenic removed from	403
Stearin, etc., Separation from Oils	288	Hydrogen as By-product of Sulphide of Zinc	536
Steel, Basic, Open Hearth Process (illus.)	586	Hydrogen in Coal Gas	665
Carbon in	281	Hydrogen, Sulphur from	117
Cellular Structure of Cast	406	Sulphuric Acid, Anhydrous (illus.)	198
Crucible	676	Acid, Concentration of (illus.)	499, 500
Furnace Heated by Flame (illus.)	675	Acid, Estimation of Free, in Vinegar	464
Gases in	675	Acid Manufacture	198, 499
Influence of Hardness on Magnetic Properties	222	Acid Manufacture (illus.)	210
Iron distinguished from	138	Acid Manufacture in the United States	26
Malleable	223	Acid as a Manure	212, 345
Manufacture (illus.)	122, 319	Acid, Purifying	456
Melting	715	Acid Recovery of Nitrous Compounds from (illus.)	456
Progress of Basic Process	746	Acid, Solubility of Nitric Oxide in	417
Self-hardening	746	Acid, Using Blower for Gases	494
Siemens-Martin Process	56	Anhydride from Chamber Crystals	116
Tempering	222	Anhydride, Estimation of (illus.)	320
Variation in Elasticity of	600	Anhydride, Specific Gravity of	573
Still for Coal-tar	671	Sulphurous Acid in Air of Towns	455, 462
Stills	201	Acid Effect on Vegetation	510
Self-sealing Lids	201	Acid from Furnace Gases	674
Stone, Artificial	120, 216, 335	Acid, Loss of Alkali caused by	498
Colouring for Building	458	Acid, Percentage in Aqueous Solutions (illus.)	303
Marble, etc., Coloured	335	Acid, Products in Inventions Exhibition	521
Stopecks, Air-tight (illus.)	578	Acid, Treatment of Wine with (illus.)	462
Strainer for Gas, etc.	197	Sunflower Seeds as Fodder for Cows	128
Straw, Bleaching and Dyeing	587	Superphosphate, Alumina in	386
Gunpowder made with Carbonised	754	Superphosphates, Manufacture	538
Nitration of	366	Reversion of Phosphoric Acid in	484
Strength of Cotton at various Stages	510	Syphons, Acids, etc. (illus.)	184
Strontia, Carbonate, Decarbonating	674	Syphon and Filter combined	134
Decarbonating Carbonate of	117	Syrups, Purification of	748
Hydrate Manufacture	395, 745	Table, Gas References, extended	690
Method, Liquors from, as Manure	132	Tallow, Specific Gravity at 100° C.	601
Treatment of Saccharine Liquors	308	Tannin Destroyed by Boiling	266
Strontium Hydrate (illus.)	344	Dyeing by means of	455
Oxide	402	Estimation	263
Oxide Manufacture (illus.)	610	Extracts, Purification of	747
Strychnia, Paraldehyde as an Antidote for	125	Synthesis	249
Strychnine	688	Tanning	672
And Brucine, Relation between	534	Tanning, Constitution of	583
Detection of	362	Tar Acid, Utilisation of	738
Sugar and Acids in Must	337	From Blast Furnaces, Examination of	581
Bleaching	461	From Blast Furnace Gases	337
Cane cultivated in Hungary	133, 358	From Coke Ovens	451, 452
Cane, Treatment of	355	From Coke Ovens, Investigation of	611
Beet Culture	504	Tartar, Adulteration of	207
Beet Farming	509	Emetic Substitute	400
Beet, Phosphates for	566	Emetic, Value as Mordant	400
Clarified by Superphosphate	411	Industry, Italian	544
From Cotton Cake	748	Tartaric Acid in Baking Powders, Substitute for	552
Detection of Cane in Milk	332	Acid Determined in Citric Acid	264
Diffusion Residues from	291	Tea, Tannin in	82, 81
Extracted from Megass	355, 461	Technology, Instruction in Chemical	323
Extracted from Mucasses	412	Temperatures of Destructive Distillation, Limiting	438
Factories, Refuse Water from	543	Terephthalic Acid	438
Ferment, which does not Invert Raw	291	Terpenes, Decomposition by Heat	416
Invert, from Saccharose	680	Tetrahydroquinoline	63
Manufacture (illus.)	541	Tetramethylthiobenzophenone, Colours from	279
Manufacture without Charcoal	542	Tetrazolodiphenyl, Derivatives with Naphthylamine	278
Manufacture of Cube and Lump	683	Thallin, Manufacture of	41
Manufacture of Lump	748	Thalpotasimeter	368
Manufacture, Mixer and Elevator	257	Thermometer for High Temperatures (illus.)	15, 189, 194, 655
Plus	356	Registering (illus.)	194
Potash and Lime Salts in	461	Maximum and Minimum (illus.)	40, 43
Purification	606	Thermometers, Air (illus.)	193
Refineries, Microbes in Filters of	607	Rise of Zero Point	418
Refineries, Waste Waters of	232	Thermo-regulator (illus.)	668, 737
In Roots, Formation of	747	Thermometer (illus.)	398
Rotation of Invert	748	Thioaniline, Derivatives of	126
Solution, Evaporator for	110	Thiocyanates, Effects on Vegetation	673
Syrup, Effect of Charcoal on	505	Thiodiphenylamine	671
"Trio"	58	Thionol	270
Beet, Cultivation in England in 1881	541	Thiophen	333, 334, 335, 740
Sugars, Nomenclature for	281	Compounds	113
Sulphates, Action of Ferric Oxide at a High Temperature	322	Derivatives	739
Manufacture of	223	Derivatives, Synthesis of	202
Of Metals, Treatment of	549	Dibromo	202
Treatment of Wood with	453	And Nitration of	209
Sulpho-colouring Matters produced by Electrolysis	397	Carbolic Acid	270
Sulphophthalic Acid	412	Preparation of	270
Sulphur, Action on Oidium Fungoid	414	Nitro	269
Action on Wine	522	Reduction of Nitro to Amido	740
From Alkali Waste	633	Synthesis	269
In Coal-gas	154	Thiophene	269
Colouring Matters containing	393	Thiophene, Preparation of	334
Compounds of Calcium	650	Thiophenols	269
Determination in Iron	213	Thioxen	279
Dioxite, Arrangement for Dissolving	351	From Coal Tar	279
Eliminated from Iron Ores	119, 573, 724	Preparation of	458
Estimated in Pyrites	187	Tiles, Coating or Surfacing	103
From Furnace Gases	635	Glazing Dutch	347
Harcourt's Colour-test for	275	Manufacture of Fluide (illus.)	97
Manufacture of Colours containing (illus.)	26	Tin, Absorption of Bromine by	225
Ores in the United States	497	Plate Manufacture	104, 106
From Pyrites	329	Removed from Scrap	223, 600
In Pyrites, Estimation of	173	Salt, Manufacture	592
Recovery from Alkali Waste	114	From Scrap by Electric Action	312
Recovery from Soda Waste, Experiments (illus.)	209		
Recovery from Soda Waste	31		
Recovery, Discussion on

## LIST OF MEMBERS.

## A

Abel, Sir F. A., Royal Arsenal, Woolwich, London, S.E.  
 Abney, W. de W.  
 Abraham, A. C., 87, Bold Street, Liverpool  
 Adam, A. Learmouth, 18, Robertson St., Greenock, N.B.  
 Adams, M. A., Ashford Road, Maidstone, Kent  
 Adams, J. W., 74, Oxford Street, Regent Road, Salford, Manchester  
 Addenbrooke, Edwin, 18, Cawley Rd., South Hackney, E.  
 Addie, J., Langloan Ironworks, Coatbridge, N.B.  
 Adkins, H., Chemical Works, Smethwick  
 Atleek, J., Mill House, Woolton, near Liverpool  
 Aikman, Charles M., Middlefield House, Partick Hill, Glasgow  
 Ainscow, H., Messrs. Thos. Vickers & Sons, Phosphate Works, Widnes.  
 Ainsworth, Thos., Holly Bank, Rochdale Road, Bury  
 Aitken, A. P., 8, Clyde Street, Edinburgh  
 Aitken, Henry, Danoch, Falkirk, N.B.  
 Akitt, Thomas, 3, Victoria Road, Lenzie, N.B.  
 Albright, G. S., The Elms, Park Road, Edgbaston  
 Albright, W. A., Maricmont, Birmingham  
 Alexander, J. O., Phn. Tuschen de Vrienden, West Coast, Demerara  
 Alexander, W. T.  
 Allan, Jno., 2, Blythwood Villas, Crouch Hill, London, N.  
 Aldred, C. H., 35, Crisp Terrace, Upper Park Road, Plumstead Common, Kent  
 Allen, A. H., 6, Ash Mount, Broom Hill, Sheffield  
 Allen, J., 164, Upper North Street, Poplar, London, E.  
 Allen, J., Fenwick, Newham, Whalley Range, Manchester  
 Allen, Wm., Edenholme, Bournemouth, Hants  
 Allen, W. H., 38, Church Street, Toronto, Canada  
 Allender, G. M., Solna, Southampton, S.W.  
 Allhusen, A., Gateshead  
 Allhusen, Wilton, 102, Quay Side, Newcastle-on-Tyne  
 Alsberg, M. (Sondheim, Alsberg & Co.), P.O. Box 2,437, New York, U.S.A.  
 Anderson, C. Torre, Messrs. Bass & Co., Burton-on-Trent  
 Anderson, Geo. B., Victoria Square, Felling-on-Tyne  
 Anderson, John, 138, Bath Street, Glasgow  
 Anderson, G. H., Howendyke, Howden, Yorks.  
 Angell, J., The Grammar School, Manchester  
 Angus, James, Lugar, Ayrshire, N.B.  
 Angus, John, 47, Lime Street, E.C.  
 Angus, W. Mathwin, St. John's Leather Works, Newcastle-on-Tyne  
 Annandale, J. H., Polton, Midlothian, N.B.  
 Ansdell, G., Collingwood Tower, near Farnboro', Hants  
 Ansdell, T. C., Kearsley Cottage, Farnworth, Bolton  
 Archbold, George, Chemical and Optical Laboratories, Oswego City, New York, U.S.A.  
 Archbutt, L., Argyle Terrace, Rose Hill, Derby  
 Armstrong, H. E., London Institution, Finsbury, London, E.C.  
 Armstrong, Sir William G., Newcastle-upon-Tyne

Arnott, G. W., Messrs. Arnott and Button, Rainham, Essex  
 Arthur, W., Ringsend, Dublin, Ireland  
 Ashwell, J. R., Midanbury Lodge, Bentinck Road, The Forest, Nottingham  
 Ashworth, L., The Barlows, Radcliffe, near Manchester  
 Aston, Theo., 11, New Square, Lincoln's Inn, London  
 Atkins, S. R., Market Place, Salisbury  
 Atkinson, Geo., Aldersgate Chemical Works, Southa II, Middlesex  
 Atkinson, R. W., 44, Loudoun Square, Cardiff  
 Atkinson, W. H., 156, Camberwell Road, London, S.E.  
 Attfield, J., Ashlands, Watford, Hertfordshire  
 Aubrey, W. H., c/o C. Norfolk, Esq., 1, Cliff Terrace, St. John's, London, S.E.  
 Auerbach, C. G., Farbenfabriken vorm. F. Bayer & Co., Elberfeld, Germany  
 Austin, E., 126, Bermondsey Street, London, S.E.

## B

Baggallay, Arthur, Cossipore, Calcutta, India  
 Bailey, Wm., The Terrace, Oakley, near Wolverhampton  
 Bailey, G. H., Barnard Castle, co. Durham  
 Baker, E., Stoneleigh, Eastern Avenue, Reading, Berks  
 Baker, Harry, 262, Plymouth Grove, Manchester  
 Baker, W. G., Garden Wharf, Church Road, Battersea, London, S.W.  
 Bald, J. H., Braddock, Pa., U.S.A.  
 Ball, T. B., 12, Edmund Street, Rochdale  
 Ballard, E. G., Queen's Park, St. Helens  
 Ballard, J. F., Somerby Villa, Norfolk Park, Maidenhead  
 Bahner, Thomas, Laburnum Cottage, Halewood, near Liverpool  
 Bamber, H. K., 5, Westminster Chambers, Victoria Street, London, S.W.  
 Banister, H. C., 31, Dale Street, Liverpool  
 Bannister, R., The Laboratory, Somerset House, London, W.C.  
 Bannister, W., 108, Patrick Street, Cork, Ireland  
 Barclay, H., Rose Hill, Harrington, Cumberland  
 Barclay, Thos., 17, Bull Street, Birmingham  
 Barlow, E., Ivy Lodge, 235, Norwood Road, Herne Hill, S.E.  
 Barnes, H. J., Phoenix Chemical Works, Hackney Wick, E.  
 Barnes, J., 37, Avenue Parade, Accrington, Lancashire  
 Barnes, Jonathan, Buckton Vale, near Stalybridge, Cheshire  
 Barnes, R. L., Lancaster House, Savoy, W.C.  
 Barr, J., Dinting Vale, Glossop  
 Barr, R., 10, Kersland Terrace, Hillhead, Glasgow  
 Barrett, E. L., 53, Springfield Road, St. John's Wood, London  
 Barrow, J., Clayton, near Manchester  
 Bartholomew, G., Halston House, Windsor Road, Forest Gate, London, E.  
 Bassett, H., 26, Belitha Villas, Barnsbury, N.

- Bateson, Percy, Emsworth, Wavertree, Liverpool  
 Battershall, Jesse P., 402, Washington Street, New York, U.S.A.  
 Baxter, W. H., The Lawn, Brixton Hill, London, S.W.  
 Bayley, F. S., 88, King Street, Manchester  
 Bayley, Thos., 7, West End Chambers, Broad Street Corner, Birmingham  
 Baynes, J., jun., Royal Chambers, Seale Lane, Hull  
 Beanes, E., Moatlands, Paddock Wood, Brenclyde, Kent  
 Beardmore, Wm., Parkhead Forge, Glasgow  
 Beaven, E. S., 5, Boreham Terrace, Warrminster, Wilts  
 Beecher, M., The Manbré Saccharine Co., Limited, Fulham Road, Hammersmith, London, W.  
 Beckett, G. H., 277, Edgware Road, London, W.  
 Beckett, J. H., Miles Plating Chemical Works, Miles Plating, Manchester  
 Beckingham, J. H., Messrs. Scott Brothers, Royal Insurance Buildings, Newcastle-on-Tyne  
 Bedford, J., Woodhouse Cliff, Leeds  
 Bedson, P. P., Durham College of Science, Newcastle-on-Tyne  
 Beilby, G., The Birches, Midealder, N.B.  
 Bell, C. Lowthian, Middlesbrough-on-Tees  
 Bell, G., Runcorn Soap and Alkali Co., Runcorn  
 Bell, H. S., 6, Dents Rd., Wandsworth Common, S.W.  
 Bell, J., Carter, Bankfield, The Cliff, Higher Broughton, Manchester  
 Bell, J. Lowthian, Rounton Grange, Northallerton  
 Bell, O., 13, Northumberland Terrace, Tynemouth  
 Bell, T. Hugh, Middlesbrough-on-Tees  
 Bell, T. L. G., Abbey Mills, Stratford, London, E.  
 Bellingham, Wm., Dalston Distillery, London, E.  
 Bendix, D., The British Alizarin Co., Limited, Silvertown, Victoria Docks, London, E.  
 Bengier, F. B., 7, Exchange Street, Manchester  
 Benjamin, M., 43, East 67th Street, New York, U.S.A.  
 Bennett, James M., 12, Hamilton Drive, Hillhead, Glasgow  
 Bennett, Thos., Birch Vale, near Stockport  
 Bentley, J. N., Stakehill Works, Castleton, Manchester  
 Bentley, Jos., 26, Albert Road, Jarrow-on-Tyne  
 Berloc, Walter, 51, South John Street, Liverpool  
 Beringer, J. J., 10, South Terrace, Camborne, Cornwall  
 Beringer, C., Rio Tinto Assay Office, Garston, near Liverpool  
 Berkley, P. A., Grange Villa, Jarrow-on-Tyne  
 Bernays, J., 96, Newgate Street, London, E.C.  
 Berry, E. E., 8, Belle Vue, Cotham, Bristol  
 Best, T. F., Lawn Wharf, Cambridge, Middlesex  
 Bevan, A., Bryn Chemical Works, Llanelly, S. Wales  
 Bevan, E. J., Inveresk Mills, Musselburgh, N.B.  
 Bevan, I., Llanelly, S. Wales  
 Bevan, Thos., 122, Cheshire View, Broad Street, Pendleton, Lancashire  
 Beveridge, J., jun., Waterloo Road, Runcorn  
 Beverley, R. J., 8, Brownwood Park, South Hornsey, London, N.  
 Bewick, T. Burrell, Haydon Bridge, Northumberland  
 Bibby, E. V., Garston Copper Works, Garston, near Liverpool  
 Biekerdike, W. E., Clayton Grange, Wiltshire, near Blackburn  
 Bickerton, C. W., The Hollies, Bosden, near Stockport  
 Biggart, J. Wm., 29, Rathcart Street, Greenock, N.B.  
 Biggs, B., 3, Lawrence Pountney Hill, London, E.C.  
 Bihm, G. F., Pennsylvania Salt Manufacturing Co., Philadelphia, U.S.A.  
 Billing, H. S., Messrs. Burnard, Lack, & Alger, Plymouth Chemical Works, Plymouth  
 Bindschedler, R., c/o Messrs. Dobson and Barlow, Bolton, Lancashire  
 Bingley, J., Chemical Laboratory, Northampton  
 Binks, J. B., 18, Esk Street, Silloth, Cumberland  
 Binney, H. A., Sutton, St. Helens  
 Birley, R. K., Messrs. Chas. Macintosh & Co., Cambridge Street, Manchester  
 Birch, R. W., Peregrine, 2, Westminster Chambers, Victoria Street, London, S.W.  
 Bisehof, Gustav, 4, Hart St., Bloomsbury, London, W.C.  
 Bishop, Fred, 16, Abbey Road, Dalkeith, N.B.  
 Bishop, Jos. T. F., 39, Market Street, Manchester  
 Bishop, A. Conway, Three Mills Lane, Bromley-by-Bow, London, E.  
 Bishop, G. A., Royal Bank House, Coalbridge, N.B.  
 Bishop, H. W., Wigginton Road, Tamworth  
 Bishop, J. S., 6, Holly Terrace, West Hill, Highgate, London, N.  
 Black, Wm., St. Bede Chemical Co., Newcastle-upon-Tyne  
 Black, Wm., Stanrigg, Airdrie, N.B.  
 Blackwell, G. G., 26, Chapel Street, Liverpool  
 Blades, C. M., Stanley Mount, Northwich, Cheshire  
 Blagden, W. G., 1, Fenchurch Avenue, London, E.C.  
 Blake, A., 4, Akenside Terrace, Jesmond, Newcastle-on-Tyne  
 Blair, J., Irvine Bank Chemical Works, Kilmarnock, Ayrshire  
 Blake, Jas., Thames Sugar Refinery, Silvertown, E.  
 Blatherwick, Chas., Dundonald, Helensburgh, N.B.  
 Blenkinsop, W., Garden Wharf, Battersea, London, S.W.  
 Bles, A. J. S., 32, Chorlton Street, Manchester  
 Blinkhorn, W. J., 31, Grove Park, Liverpool  
 Blott, F., Christ Street, Poplar, London, E.  
 Blythe, F. C., Adswode, Accrington  
 Blythe, H. F., Holland Bank Chemical Works, Church, near Accrington  
 Blyton, J., 12, Cromford Court, Market Street, Manchester  
 Boake, A., Stratford, London, E.  
 Bolas, Thos., 8, Grove Terrace, Chiswick, W.  
 Bolton, Col. Sir Francis, 4, The Sanctuary, Westminster, S.W.  
 Bolton, G. H., Widnes Alkali Co., Limited, Widnes  
 Booth, Geo., Irk Vale Dye Works, Middleton, near Manchester  
 Borland, John, Etruria, Kilmarnock, N.B.  
 Borland, W. D., The Explosives Co., Limited, Stowmarket, Suffolk  
 Bostock, G. H., 9, Great John Street, Manchester  
 Boston, H. G., Nunthorpe Crescent, Bishopthorpe Road, York  
 Bothamley, C. H., Yorkshire College, Leeds  
 Bottinger, H. T., Elberfeld, Germany  
 Bottle, Alex., 4, Godwyne Road, Dover  
 Boulton, H. E., 64, Cannon Street, London, E.C.  
 Boulton, S. B., 64, Cannon Street, London, E.C.  
 Boulton, T. S., Mountford House, Barnsbury Square, London, N.  
 Bountill, G. R., Cloncurry Copper and Smelting Company, Cloncurry, Queensland  
 Bourcart, R., à la Boissière, près Genève, Switzerland  
 Bow, R. H., 7, South Gray Street, Edinburgh  
 Bower, G., St. Neots, Huntingdonshire  
 Bower, H., P.O. Box 946, Philadelphia, Pa., U.S.A.  
 Bowley, Jos. John, Wellington Works, Battersea Bridge, London, S.W.  
 Bowman, F. H., West Mount, Halifax  
 Bowman, R., Heworth Alkali Works, Gateshead-on-Tyne  
 Bowrey, J. J., Kingston, Jamaica, West Indies  
 Boyd, Pyralagias, Box 77, North Adams, U.S.A.  
 Boyd, W., Tharsis Works, East Woods, Cardiff  
 Boyd, W., c/o Messrs. Tennant & Co., St. Rollox, Glasgow  
 Bradbury, A., Mason's Buildings, Exchange Street East, Liverpool  
 Braden, Herman, 72, Buxton Road, Leytonstone Road, Stratford, E.  
 Bradley, N., 49 & 51, Chapman Street, Hulme, Manchester  
 Brain, N. J., Canal Street Chemical Works, Great Ancoats, Manchester  
 Bramham, W., 82, Bow Road, London, E.  
 Bramwell, E., St. Helens  
 Bramwell, Sir F., 5, Great George Street, Westminster, London, S.W.  
 Bramwell, G. H., Cowley Hill, St. Helens, Lancashire  
 Branson, F. W., 14, Commercial Street, Leeds  
 Bray, Geo., Blackman Lane, Leeds  
 Breckon, J. R., 32, Fawcett Street, Sunderland  
 Breckon, George, Irvine Chemical Co., Limited, 204, Vincent Street, Glasgow

- Brenemann, A. A., 97, Water Street, New York, U.S.A.  
 Brewis, E. T., Great Brunswick Street, Dublin  
 Brier, John, jun., Oak Bank, Bollington, near Macclesfield  
 Broad, Jas., 66, High Street, Lewes, Sussex  
 Brock, J., British Alkali Works, Widnes  
 Brookes, E. A., 15, Withington Road, Whalley Range, Manchester  
 Brooke, Edw., Oakley House, Edgerton, Huddersfield  
 Brooks, J., Bury Street, Radcliffe Close, near Manchester  
 Brotherton, E. A., Fern Cliffe, Ilkley, Yorkshire  
 Brown, A. Crum, 8, Belgrave Crescent, Edinburgh  
 Brown, D., 93, Abbey Hill, Edinburgh  
 Brown, D., Donaghmore, Tyrone, Ireland  
 Brown, H., Messrs. Grimble & Co., Vinegar Works, Cumberland Market, London, N.W.  
 Brown, J., The Chemical Works, Saville Town, Dewsbury  
 Brown, J. Campbell, 27, Abercrombie Square, Liverpool  
 Brown, J. T., 104, Edith Grove, Chelsea, London, S.W.  
 Brown, T., The Chemical Works, King's Lynn  
 Brown, H. T., 47, High Street, Burton-on-Trent  
 Brown, Walter, c/o Jas. H. Dennis & Co., Widnes  
 Brown, F. W., 35, Watterton Road, St. Peter's Park, London, W.  
 Brown, W. A., Overton Paper Mills, Greenock, N.B.  
 Browning, W., Broad Oak, Acreington  
 Brundrett, A., Rhymney Ironworks, Monmouthshire  
 Brunner, H., Cliff House, Appleton, Widnes  
 Brunner, J. T., Winnington, Northwich  
 Brunner, J. P., 28, Exchange Street East, Liverpool  
 Bryan, E., Gasworks, Beverley, East Yorkshire  
 Bryson, W. A., 20, Lombard Street, Trinity, Edinburgh  
 Buch, Carl von, 17, Cavendish Place, London, W.  
 Buchanan, J. Y., 10, Moray Place, Edinburgh  
 Buckley, W., Brookside Printworks, West Leigh, Lancashire  
 Budden, E. R., Eversley Lodge, Ealing Common, London, W.  
 Bullock, J. L., 3, Hanover Street, Hanover Square, London  
 Bamby, H., Ebbw Vale, Monmouthshire  
 Bunker, H. E., Old Burrows Road, Skewen, near Neath, South Wales  
 Burghardt, C. A., Bridgewater Club Chambers, 110, King Street, Manchester; and Owens' College, Manchester  
 Burnard, R., Plymouth Chemical Works, Plymouth  
 Burrell, B. A., Bank Chambers, 70, South Mail, Cork  
 Burton, F., 2, Green Street, Bethnal Green, E.  
 Bush, R. A., 20, Artillery Lane, London, E.C.  
 Bush, W. E., 20, Artillery Lane, London, E.C.  
 Bush, W. J., 20, Artillery Lane, London, E.C.  
 Boshell, E. D. T., Broom Hill, Great Barr, Birmingham  
 Butt, E. N., 13, Curzon Street, Mayfair, London, W.  
 Butterfield, J. C., Westbury Cottage, Barking  
 Button, H., Faraday Chemical Works, Rainham, Essex  
 Byard, A. C., 12, Brunswick Terrace, Fisher Street, Barking Road, Essex
- C**
- Cabot, Godfrey L., 11, Park Square, Boston, Mass., U.S.A.  
 Calderwood, J., 1, Alverton Villas, Wandsworth Common, London, S.W.; and Price's Patent Candle Co., Battersea  
 Caley, A. J., Chapel Field, Norwich  
 Calvert, J. H., Oakenshaw Printworks, Clayton-le-Moors, Acreington  
 Cameron, Ian, Nickel Co., Kirkintilloch, N.B.  
 Cameron, R., Priory Lodge, Blantyre, Lanarkshire  
 Cammaek, J., 10 Salisbury Street, St. Helens  
 Campbell, A., Roselands, Millbrook, near Southampton  
 Campbell, W. B., 34, Grey Street, Newcastle-on-Tyne  
 Cannon, M., Beaufoy's Chemical Works, Lavender Hill, London, S.W.  
 Carey, E., Widnes, Lancashire  
 Carlike, T., 27, St. Vincent Place, Glasgow  
 Carmody, Patrick, Laboratory, Somerset House, London, W.C.  
 Carnelly, Thos., University College, Dundee  
 Caro, H., Mannheim, Germany  
 Carpenter, H. S., 32, Holborn Viaduct, London, E.C.  
 Carpenter, R. F., Bent Terrace, Prestwich, near Manchester  
 Carpenter, W. L., 36, Craven Park, Harlesden, London, N.W.  
 Carrick, H., Redhugh Engine Works, Gateshead  
 Cartegh, M., 180, New Bond Street, London, W.  
 Caspers, Charles J., c/o Messrs. Read, Holliday & Sons, Huddersfield  
 Casson, R. Smith, The Saltwells, Brierley Hill, near Dudley  
 Castéllaz, Chas., 19, Rue Ste. Croix de la Bretonnerie, Paris  
 Cawley, G., 2, Birch Villas, Northern Grove, Didsbury, Manchester  
 Cawley, J., 278, Passaic Street, Newark, New Jersey, U.S.A.  
 Chadwick, Edmund, Wilton Mill, Blackburn  
 Chadwick, L. N., Ivy Lawn, Ponders End, Middlesex  
 Chaloner, G., 35, King's Road, Green Lanes, N.  
 Chamberlain, J., Gas Light & Coke Co., Beekton, North Woolwich, E.  
 Chambers, J. M., Te Mata, Havelock, Hawkes Bay, New Zealand  
 Chance, A. M., Alkali Works, Oldbury, near Birmingham  
 Chance, J. F., Alkali Works, Oldbury, near Birmingham  
 Chandler, Dr. C. F., School of Mines, Columbia College, New York  
 Chaney, Harry, Mortonley Hall, near Sheffield  
 Chapman, S., 84, Eccleston Square, London, S.W.; and 36, Mark Lane, E.C.  
 Chapman, W., Crescent Road, Ipswich  
 Charlton, J., Crabtree Lane, Clayton, near Manchester  
 Charlton, J., 42, Blackfriars Street, Manchester  
 Cheshire, Fred., Laboratory, Somerset House, London, W.C.  
 Chester, E. D., c/o Messrs. Farley & Co., 15, Philpott Lane, London, E.C.  
 Chidley, J. R., Abbey Mills Distillery, West Ham, Essex  
 Chinnery, G. T., Redhugh Chemical Works, Gateshead-on-Tyne  
 Christie, J., Messrs. John Orr, Ewing & Co., Alexandria Works, Dumbartonshire  
 Christopher, G., 8, Rectory Grove, Clapham, London, S.W.  
 Christy, Thos., Malvern House, Sydenham, S.E.; and 155, Fenchurch Street, London, E.C.  
 Chrystal, W. J., Shawfield Works, Rutherglen, near Glasgow  
 Clubb, Harry, 6, Prince's Square, Bayswater, London, W.  
 Church, A. H., Shelsley, Kew, Surrey  
 Claisen, L., 1, Gore Street, Greenheys, Manchester  
 Clark, E. B., Rangoon Oil Co., British Burmah  
 Clark, J., 138, Bath Street, Glasgow  
 Clark, Jno., 35, Mariners' Cottages, South Shields  
 Clark, W., 53, Chancery Lane, London  
 Claudet, A. C., 10, Oak Hill Park, Hampstead, London, N.W.  
 Claudet, F. G., The Grange, Weston, near Runcorn  
 Claus, C., 16, Mark Lane, London, E.C.; and 24, Merton Road, South Wimbledon, S.W.  
 Clayton, E. G., Chemical Laboratory, 54, Holborn Viaduct, London, E.C.  
 Clayton, F. C., 18, St. James Road, Edgbaston, Birmingham  
 Clemen, J. H., c/o Hen. Clemen, Falmouth, Cornwall  
 Clemens, G. H., Cudbear Street, Hunslet, near Leeds  
 Clerk, Dugald, Crum Ironworks, Woodside Road, Glasgow  
 Cliff, D. Y., 7, Wellington Street, Leeds  
 Cliff, J., 7, Wellington Street, Leeds  
 Cliff, Stephen, Wortley, near Leeds  
 Clift, J., Kemp Field House, Knottingley, Yorks  
 Clift, Jas., 46, Billhay Street, West Bromwich

Cloud, T. C., Wallaroo Smelting Works, Wallaroo, South Australia  
 Clowes, F., University College, Nottingham  
 Coates, John, 106, Cannon Street, London, E.C.  
 Cobb, E., 79, Cornhill, London, E.C.  
 Cochrane, Wm. P., Ormesby Ironworks, Middlesbrough; and 3, Belmont Terrace, Coatham, Redcar  
 Cockburn, J., 11, Heathcote Street, Mecklenburgh Square, London, W.C.  
 Cogswell, W. B., Syracuse, New York, U.S.A.  
 Cohen, J., Beech House, Pendleton, Manchester  
 Colby, W. H., Oakley, Ruthin Road, Denbigh  
 Coleman, J. J., 45, West Nile Street, Glasgow  
 Collens, E., 203, Ashted Row, Birmingham  
 Collins, J. H., 64, Bickerton Road, Highgate New Town, London, N.  
 Collins, John, Bradford Chambers, Mawdsley Street, Bolton-le-Moors  
 Colson, A., Gas Office, Millstone Lane, Leicester  
 Connor, C. C., Notting Hill House, Belfast, Ireland  
 Conrad, E. C., 23, Well Street, Wellclose Square, London, E.  
 Cook, E. M., 154, East 37th Street, New York, U.S.A.  
 Cook, E. R., East London Soap Works, Bow, London, E.  
 Cook, H. J., East London Soap Works, Bow, London, E.  
 Cook, Robt., Atlas Chemical Works, Widnes  
 Cooke, Leonard, Horwich Vale, near Bolton-le-Moors  
 Cooke, Saml., Poona, Bombay, India  
 Cookson, N. T., Newcastle-on-Tyne  
 Cooper, A., North-Eastern Steel Co., Middlesbrough-on-Tees; and The Laurels, Linthorpe, near Middlesbrough-on-Tees  
 Cooper, H. P., 1, Oakley Villas, Rectory Road, Hornsey, London, N.  
 Cooper, W. J., 7, Westminster Chambers, Victoria Street, S.W.  
 Corbett, E., Plaskynaston Chemical Works, Ruabon, North Wales  
 Corbett, Jno., M.P., Stoke Works, near Bromsgrove, Worcestershire  
 Cotterell, Rocke, 35a, Ann Street, Glasgow  
 Cottrell, Thos., Lombard Street West, West Bromwich

# THE JOURNAL OF THE Society of Chemical Industry:

A MONTHLY RECORD  
FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 1.—VOL. IV.

JANUARY 29, 1885.

Non-Members 30/- per annum; Members  
21/- per Set; Single Copies 2 6.

## COUNCIL.

*President:* Dr. W. H. Perkin, F.R.S.

*Vice-Presidents who have filled the Office of President:*

Sir H. E. Roscoe, Ph.D., LL.D., F.R.S.  
Sir Frederick Abel, C.B., D.C.L., F.R.S.  
Walter Weldon, F.R.S.

*Vice-Presidents:*

Alexander M. Chance.  
George E. Davis.  
Prof. James Dewar, F.R.S.  
James Duncan.  
David Gamble.  
David Howard.  
D. B. Hewitt, M.D.  
E. K. Muspratt.  
J. C. Stevenson, M.P.

*Ordinary Members of the Council:*

Eustace Carey.  
Prof. Chas. Graham, D.Sc.  
Peter Griess, Ph.D., F.R.S.  
Ivan Levinstein.  
R. Messel, Ph.D.  
B. E. R. Newlands.  
John Pattinson.  
Thomas Royle.  
John Spiller.  
Prof. W. A. Tilden, F.R.S.  
John Williams.  
P. J. Worsley.

With the Chairmen and Secretaries of Local Sections.

*Honorary Treasurer:*

E. Rider Cook, East London Soapworks, Bow, E.

*Honorary Foreign Secretary:*

Ludwig Mond, 28, Park Crescent, Portland Place, W.

*General Secretary:*

Charles G. Cresswell, Palace Chambers, 9, Bridge Street,  
Westminster.

## THE JOURNAL.

*Publication Committee:*

The President.

## NOTICES.

Authors of papers printed in the Journal are hereby notified of the fact that, in accordance with Bye-law 43, they are entitled to receive not more than 50 gratuitous copies of their papers. Authors should state on their manuscripts their desire to have free copies, adding the number wished for. Unless the contrary be specially desired, this being stated on the manuscript, the reprints of an author's paper will not include the report of any discussion that may have arisen after the reading of the paper.

Members are hereby advised that the Subscription for 1885 falls due at the beginning of the year, and should be paid as soon afterwards as possible. The Council has decided that after January 1st, 1885, the 29th Bye-law will be strictly enforced, so that Members whose subscriptions are more than four months in arrear, will not continue to receive the Society's Journal.

## LIST OF MEMBERS ELECTED JAN. 23rd, 1885.

John Allan, 2, Blythwood Villas, Crouch Hill, N., journalist.  
R. K. Birley, Messrs, Chas. Mackintosh & Co., Cambridge Street, Manchester, india rubber maker.  
Col. Sir Francis Bolton, C.E., 4, The Sanctuary, Westminster, S.W.  
W. A. Brown, Overton Paper Mills, Greenock, N.B., paper maker.  
Harry Chaney, Mortomley Hall, Sheffield, technical chemist.  
E. M. Cook, 151, East 37th Street, New York, U.S.A., chemical manufacturer.  
Roke Cottrell, 35A, Ann Street, Glasgow, glass silvers.  
F. M. Davies, 3, Glenmoir Terrace, Hyde Vale, Greenwich, S.E.  
Chas. Davis, 15, Vespasian Terrace, Roman Road, East Ham, E., chemist.  
S. P. Eastick, Chemical Works, Phoenix Wharf, Millwall, E., chemist.  
H. W. Fenner, 7, Vanbrugh Park Road West, Blackheath, S.E., chemical manufacturer.  
Major Lamorock Flower, 12, Finsbury Circus, E.C., sanitary engineer.  
E. Le Breton Gardiner, Passaic, New Jersey, U.S.A., woollen manufacturer.  
Frank Gossling, The Patent Office, Southampton Buildings, Chancery Lane, W.C.  
Saml. M. Gray, City Hall, Providence, R.I., U.S.A., civil engineer.  
Charles Harvey, 60, Blackfriars Road, S.E., washing blue manufacturer.  
Walter J. G. Hillier, Bristol Channel Chemical Company, Minehead, Somerset.  
Chas. H. Hutchinson, Albert Works, Church Street, Barnsley, Yorks, gas engineer.  
Jno. Johnson, Franklin Square and Cherry Street, New York, U.S.A., chemical engineer.  
Dr. Wm. Kellner, 13, Clarendon Villas, Old Charlton, S.E., chemist, war department.  
Jas. C. Kingdon, 30, Victoria Road, Old Charlton, S.E., chemist.  
John Lyle, 42, Ellison Road, Streatham, S.W., sugar refiner.  
T. E. Mackenzie, 10, Willow-bank Crescent, Glasgow, analyst.  
R. W. Mahon, 110, Arch Street, Camden, N.J., U.S.A., chemical manufacturer.  
Hugh McGilivray, Rockingham Gasworks, Birdwell, near Barnsley, manager.  
Edw. A. Petherick, 17, Warwick Square, Paternoster Row, E.C., bookseller.

T. C. Sanderson, 31, Hatcham Park Road, New Cross, S.E., technical chemist.  
 Herb. Trewby, Langford Lodge, New Park Road, Clapham Park, S.W., chemist.  
 J. L. Vaughan, Woodleigh, East Dulwich Grove, S.E., chemical manager.  
 R. W. Walker, Quarlon Vale Printworks, Turton, near Bolton, calico printer.  
 T. Lloyd Whiteley, University College, Nottingham, lecturer technology.  
 A. E. Wilson, Scunthorpe, Doncaster, metallurgical chemist.

#### CHANGES OF ADDRESS.

G. B. Anderson (l/o Runcorn), Victoria Square, Felling-on-Tyne.  
 J. F. Ballard (l/o Sidecup), Somerby Villa, Norfolk Park, Maidenhead.  
 S. B. Bell (l/o Queen Victoria Street), 6, Dent's Road, Wandsworth Common, S.W.  
 Dr. L. Claissen (l/o Dover Street), 1, Gore Street, Greenheys, Manchester.  
 B. Dawson (l/o The Laurels), York House, Malvern Link, Worcestershire.  
 Wm. Donald (l/o Kennel Vale), c/o J. B. Aitken, Esq., Dockhead Street, Saltcoats, N.B.  
 Chas. Ekin (l/o Hounslow), 1 Park Road, Surbiton.  
 D. Frazer (l/o 113, 127, Buchanan Street, Glasgow.  
 C. H. Green (l/o Lydia Ann Street), 7, York Street, Liverpool.  
 Jos. Hall (l/o Prescot), Park Villa, Queen's Park, St. Helens.  
 Robert Hamilton (l/o Lugar), Muirkirk Ironworks, Muirkirk, N.B.  
 W. B. Harrington (l/o Montenotte), Ardsullagh, Old Blackrock Road, Cork.  
 Thos. Holliday (l/o Dudley Road), Clifton Villa, High Street, West Bromwich.  
 Dr. L. Landsberg (l/o South Kensington), Offenbach-am-Main, Germany.  
 C. G. Warnford Lock (l/o Charing Cross), 125, Strand, London, W.C.  
 W. Jesse Lovett (l/o Birmingham), 17, Firs Hill Road, Pitts-moor, Sheffield.  
 T. W. Lovibond (l/o Lee), Beaumont House, Newark-on-Trent.  
 J. L. Muspratt (l/o Widnes), Trelawney House, Flint, North Wales.  
 G. H. Ogston, Junior Athenæum Club, Piccadilly, London, W.  
 D. J. Pinkerton (l/o Glasgow), Gas Works, Paisley, N.B.  
 Wm. Pringle (l/o West Bromptou), Rhiwderin, Newport, Monmouthshire.  
 H. A. Rademacher (l/o Turn Lee Paper Mills), 77 Charles-town, Glasgow.  
 Chas. Renard (l/o Rue Grignan), L'Estaque, Marseilles, France.  
 Dr. E. H. Rennie (l/o Sydney), University of Adelaide, South Australia.  
 E. Solvay (l/o Rue du Prince Royal), 19, Rue du Prince Albert, Brussels.  
 T. Venables (l/o Kelvinside), Parkburn Chemical Works, Kirkintilloch, N.B.  
 John Williams, 11, Buckingham Street, W.C.  
 J. Lainsan Wills (l/o Caylus), Laboratory, St. Antonin, Yarn et Garonne, France.  
 C. Francis Young (l/o Moss Bank), 13, Manchester Old Road, Middleton, Manchester.

#### CHANGES OF ADDRESS REQUIRED.

E. V. Miller, 1 Love Lane Sugar Refinery, Liverpool, now in New Zealand.  
 Jno. Robinson, 1/o Devon Square, Newton Abbot.

### Deaths.

Geo. Cranston, junr., 1/o 125, Sanchiehall Street, Glasgow.  
 Joseph Turnbull, 1/o 37, West George Street, Glasgow.

### London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: David Howard.

#### Committee:

Sir F. A. Abel.	P. E. R. Newlands
H. E. Armstrong.	B. Redwood.
W. Crowder.	T. Royle.
C. Graham.	John Spiller.
S. Hall.	G. C. Trewby.
A. K. Huntington.	W. Weldon.
R. Messel.	J. Williams.

Local Sec. and Treasurer: Thos. Tyrer, Garden Wharf, Church Road, Battersea, W.

MEETINGS, SESSION 1885—First Monday in each month (unless otherwise indicated).

February 2.—Mr. Roverton Redwood on "The Russian Petroleum Industry and Products therefrom."

Notices of papers and communications for the meetings to be sent to the Local Secretary.

Monday, January 5th, 1885.

MR. DAVID HOWARD IN THE CHAIR.

REFERENCE was made to the decease of Sir Henry Roscoe's son at Magdalen College, Oxford, and a resolution of sympathy and condolence with Sir Henry and his family unanimously agreed to.

Mr. C. N. CRESSWELL (barrister-at-law), on rising to open the discussion on "The Proposed Rivers Pollution Bill," said: The subject of rivers pollution has attracted the attention of the civilized world, for the last quarter of a century, and during the last ten years has assumed such proportions that it has even received the attention of the legislature of the country. It had been attacked before in the scientific field, in 1868 by the Rivers Pollution Commission, and by a second Royal Commission in 1870, and the result of all these forces, commercial, agricultural, and scientific combined, was the enactment in 1876 of that which is known as the Rivers Pollution Prevention Act. The chief delinquents throughout this country who had brought about the state of things which led to this legislation, were the Boards of Health, who had been specially constituted to promote the health of the people, and to prevent the pollution of rivers. Amongst them, and most conspicuous by its dereliction of duty, was the great Metropolis itself, the emporium of commerce, and in the opinion of some the centre of civilization, at this moment in the throes of a revolution of public feeling which may perchance bring about some redress for a flagrant evil. Meanwhile the Metropolis always has been, and to this day is the greatest offender against those laws which are supposed to lie at the root of all sanitary progress and improvement. After the Act was passed I was invited by the Society of Arts to read a paper at one of its numerous health congresses, attended by representative men from all parts of the country; and in 1880 I was induced to become a member of the Executive Committee, under the Presidency of the Right Hon. James Stansfeld, M.P., himself connected with the industrial interests of this country. With him was arranged the programme of the conference, and *inter alia* a resolution insisting upon the necessity for considerable amendments in the Rivers Pollution Prevention Act of 1876. It had already been described in a paper read before that Society as a "piece of lame and impotent legislation," and I have never yet seen reason to change that opinion. Whereas it was designed for the purpose of preventing a great national evil, it has in fact—whether by defects of draughtsmanship, or the design of the promoters, I know not—contributed to legalize that which had hitherto been unlawful and preventable at common law; and it has given facilities to those who wished to transgress its provisions or disregard their own self-interests—opportunities which they never previously enjoyed. As a matter of fact the Act has seldom been put in force. It would be untrue to say that it has never been enforced, but in a return which was published at the instance of the Duke of Northumberland about twelve months ago, I find that during the six years in which that Act is supposed to have been in operation attempts have been made on 53 occasions only. Of these 53 proceedings there have been 24 orders to restrain pollution, which have been obtained, but have never been enforced at all. Twelve of them have been obtained at the instance of two particular authorities, the Over-Darwen and the Aire and Calder Navigation. Nineteen of them were obtained against Local Boards, Corporations, or Sanitary Authorities, to whom the duty of enforcing the Act

is committed by the Legislature. These cases have occurred only in 15 counties, so that there remain in Great Britain 37 counties in which no steps whatever have been taken to repress pollution, although in many of them it exists, and in its most aggravated forms, especially in Scotland. The ingenuity of lawyers and others soon detected loop holes in the Act, and it may be convenient to mention one or more of them, since it is for the purpose of remedying those defects that the present bill, which is now before us, has been projected. The prime defect of the Act is that to which I have already alluded, viz., the want of proper machinery for carrying it into execution. Any person aggrieved was constrained to lay his case before the sanitary authorities, probably much greater delinquents than anyone else in the district. Naturally they were reluctant to put in force an Act which might be used very speedily against themselves. However in the event of that sanitary authority refusing the aid of their influence and resources (for it was to a great extent a question of resources), he could have recourse to the Local Government Board, and that department, if it were so minded, had the power of compelling the sanitary authority to put the Act in force. I know of a few cases in which that course has been attempted, and in each one the authority deemed the proceedings to be at least premature. Now, when any person, manufacturer, or sanitary authority had violated the Act, the first thing to be done was to serve him with legal notice. He, on the other hand, if well advised, anticipated the action of the authorities by giving also notice to the Local Government Board, asking that an inspector might come down and visit his premises. Of course during that period the Act is practically superseded, which was intended to give protection to the public from these and such like delinquencies. In every case you will find that something of the same sort has been done. For this reason the promoters of this bill have sought to curtail the dispensing power of the Local Government Board by leaving it to the Court to determine whether upon the report of the Local Government Inspector any extension of time should be given at all, and if opportunity for improvement be given, by limiting the period to six months. The second difficulty of the Act was in its definitions. In the enacting clause it had spoken continuously of liquid matters, and of solid matters—of liquid sewage matters, and of solid polluting matters: in fact they had used the words liquid and solid redundantly throughout, and had defined the word solid, negatively “It shall not include particles of matter in suspension in water.” I well recollect hearing that illustrious chemist, the late Dr. Voelcker, say, in remarking on a paper I directed to this subject, that he knew of no more fertile source of pollution than matter held in suspension in water, and that if that were exempted from the operation of the statute, the statute was nugatory. He cited many instances. Some of us know a cause of alleged pollution in the south-west of England, viz., the washings from china clay works, which consist mainly of matter held in suspension in water. It cannot be asserted that the matter itself is polluting; at all events authorities differ on the subject; some contend that it is; but it is doubtful whether it could be held in law to be “polluting matter.” There cannot, however, be a doubt that the continual deposition of mica, and other matters in suspension, is gradually silting up the rivers of West Devon and Cornwall, an evil which is becoming more aggravated every day. Nevertheless I see great difficulty in enforcing the Act against manufacturers of china clay in that district, and for this reason: There are clauses in the Act

which prohibit you from putting anything in the nature of a solid into the bed of a river so as to cause obstruction to navigation. These waste waters have undoubtedly caused obstruction to navigation, and well-nigh choked the rivers in some parts of Cornwall, yet they cannot be treated as solids, because the Act declares that that which is held in suspension in water is not included in the words “solid matter.” When the question was raised whether you could not bring to bear the polluting liquid clauses on that peculiar case the legal objection was taken, that as the liquid itself was pure, and the matter held in suspension was neither a solid nor polluting it would not come within the provisions of the statute, or any part of it. These definitions of liquid solids are expunged from the present bill now before the House. If public policy determine that the rivers are to be preserved from pollution, it is clear to all lawyers that it cannot be done under the Act of 1876. There are other defects, indeed it may be said that the Act bristles with them. I will, however, confine myself to those salient points which have been already under the cognizance of the courts. In the clauses which define an offence, the word “knowingly,” a word well known to legal scholars, is continually used. It is difficult to conceive how a man can be said to be guilty of an offence if he did a thing unknowingly. As the Act is always construed strictly, that little superfluous word has again and again been utilized successfully to shield wrong-doers from the consequences of their acts, and it is of course excluded from this bill, which has been brought in by Mr. G. W. Hastings (one of the members for Worcestershire), Earl Percy, and Colonel Walrond. The latter represents a body of gentlemen who have felt themselves aggrieved by pollutions in South Devon. Earl Percy represents the northern counties, whilst Mr. Hastings was for years the president of the Social Science Association. Let us take the bill and notice—first, section 2, in which is defined in the simplest possible terms that which constitutes “an offence” under the Act. Now in 1876 for the first time it is declared to be an offence, and in the bill it is constituted an offence in one section, instead of three, and in unequivocal terms. The old Act is simplified in every direction, both as regards definition and procedure. Every person who puts or permits to fall into the river any solid matter which shall interfere with its due flow, (2nd) so “that it shall alter its bed, and (thirdly) so that it shall pollute its waters shall be guilty of an offence.” One cannot imagine any solid matter, whether in suspension or not, that could harm a river, except in all or one of those three ways mentioned. It then proceeds to use the words “any liquid or solid sewage matter.” In my opinion it would have been better to have written simply “any sewage matter.” Surely it is the matter which causes the evil, and whether it be in a liquid or solid form seems to me to be immaterial. Then it goes on to say “any liquid containing matter poisonous, noxious, polluting, or injurious to animal life, from any manufactory, manufacturing process, mine, or place where any trade, business, or occupation is carried on.” Hitherto there have been special clauses for mines, and as they were singularly ill drawn there have always been means found for evading them. The whole pith of the Act is in these sub-sections, and it is for the manufacturing industries to consider whether there be any valid objection to these clauses; if they pass, all the rest is mere procedure and clauses for carrying them into effect. But the machinery itself is improved. Neither the local sanitary authority nor the Local Government Board are necessary parties. It is simply whether

you are an aggrieved person, incorporated or unincorporated, and every possible known entity is, I believe, embraced within those words. They include the National Fishery Associations, who are not corporations in the ordinary sense of the term, friendly societies, town councils, or a board of health. In fact, everyone who feels aggrieved may come at once to the nearest Court and ask for redress, and it is in the power of the Court to make proper inquiries, ascertain the facts, inviting, if they will, scientific assistance, and then to adjudge a penalty not exceeding £50 a day. The Local Government Board, at the instance of the defendant, may send down an inspector to inquire; but the inspector's certificate is not, as before, conclusive evidence in the defendant's favour. Hitherto in every case certificates have been granted with more or less onerous conditions, and proceedings have been stayed. Now it is for the Court, in its discretion, by Clause 3, to do that which is just, providing they do not give an interval of more than six months during which the means of prevention may be improved. There is an appeal, of course, as there ought to be where any Court is invested with powers such as these. There was a Clause 6 in the Act of 1876, which I approach with some hesitation in an assembly such as this—inserted without doubt by representatives of the industrial interests in the House of Commons; and the qualifications intruded into that clause probably assisted the Act much in its passage through Parliament. This clause enacts that before giving consent to proceedings, the Local Government Board shall be satisfied that means are in fact available for preventing the alleged pollution, and that due regard shall in each particular case be had to the industrial interests of the district. Inasmuch as from the point of view of the manufacturers those industrial interests are supreme, whilst the National Fishery Associations and various agricultural interests are most probably of a different opinion, it is not within my province at the present juncture to express an opinion one way or the other; but inasmuch as from the point of view of industrial interests nothing could supersede the importance to the State of their existence, the result anticipated from the outset has invariably happened, and in construing this clause with regard to the interests of each industry the Department has been affected by political rather than sanitary considerations. As to Clause 7, I fail to see its importance. It seems to me whether you send polluting matters through an old channel, or a new one, it is polluting matter still, and the river suffers, and if it be desirable to amend that state of things it cannot be desirable to clog it with these complexities. Finally, as to Clause 9, which peculiarly affects the interests which you represent here to-night. It defines the so-called standards of purity, giving the minimum impurity which will be permitted; and affords a test of the measure and limit of pollution, defined, as the promoters think that it should be, by the Act itself. The definitions, if not word for word identical with those of the Rivers Pollution Commissioners', are based upon them. On the other hand, I have authority for saying that they were approved by no less an authority than Sir Lyon Playfair, and from the point of view of the representative of the University of Edinburgh, they represent the maximum of concession which can be given to the manufacturing industries of this country. Whether those industries by their representatives in Parliament will be content to accept that which the providential wisdom of great chemists will send them is another question; but I would submit to you that they are of grave importance to your interests, and that if you could by a committee appointed for the

purpose, or by the machinery of your own association, express either approbation or disapprobation to those who are charged with the carrying of the bill through Parliament, I am convinced that every suggestion which you might make would be received with gratitude, and with a desire to conciliate the various interests which are so largely represented here this evening.

The CHAIRMEN said that they were much indebted to Mr. Cresswell for his able explanation of the proposed bill, but he could not help thinking that such purity as it sought could only be secured by the extinction of a large proportion of the industries of the country. The gravest fault of the bill was that it took no account of varying circumstances, but laid down rigid and impracticable standards. Another grievous fault was the proposal that any individual might gratify private malice by instituting a lawsuit at the public expense. After all, so-called sanitary authorities were the great offenders and not chemical manufacturers.

Mr. NEWLANDS said there was one clause defining the standards of purity, which he thought required more consideration. Sub-section A of Clause 9 referred to any liquid which contained in suspension more than one part by weight of dry organic matter in 100,000 parts by weight of the liquid, but the great bulk of the rivers in the Kingdom below locks contained more than that as suspended mud. Then sub-section C prohibits the introduction of any liquid which shall exhibit by daylight a distinct colour when a stratum, one inch deep, is placed in a white porcelain or earthenware vessel. Now, a stratum of Thames water, taken at Victoria Docks, one inch deep, in a porcelain vessel, was anything but clear, and even the water used at Greenock, which was very pure in most respects, was highly coloured.

Mr. JOHNSON said: They ought to give an opinion upon the Bill in no uncertain tone. To Clause 5, he had three distinct objections: Firstly, the bill said: It would be the duty of the sanitary authority upon complaint of certain parties, to institute proceedings for offences against the Act; but Mr. Cresswell had told them that the sanitary authorities were the principal polluters of streams, and if they were the sole persons to prosecute offenders, they must, from necessity, prosecute themselves, which he thought was bad in English law. The next was: That the obligation to proceed on frivolous, vindictive, or malicious complaints, was unjust to the local authorities and far more so to the manufacturer against whom a frivolous complaint might be made, and in the event of the refusal of the sanitary authority to institute proceedings accordingly, complainant might make an *ex parte* application to the Court for permission to proceed at the expense of the sanitary authority. This was a great power for evil to place in the hands of any individual; but there was even a worse injustice than this, for Clause 3 said: That any person making default in complying with the requirements of an order shall pay to the person complaining a sum not exceeding £50 a day. Therefore there would be a strong motive to avaricious, needy and unprincipled persons to bring complaints. It seemed to him a great defect that the complainant in such cases should be empowered to move the Court for leave to institute proceedings at the expense of the sanitary authority, without giving notice; firstly, to the sanitary authority, and secondly, to the manufacturer, who it would be alleged had polluted the stream, and both should have leave to show cause why the permission of the Court should be withheld. The next clause he would notice was Clause 6 which

provided for an enquiry by the Local Government Board, but it did not state that the individual against whom an order had been obtained should have power to call in the Local Government Board and insist on an enquiry being made in his case. Mr. Cresswell said the words were, "If desirable in the opinion of the Local Government Board." Of course the Local Government Board could not express any desire or form any opinion unless they were put in motion. Mr. Johnson also pointed out that it did not provide at whose expense the enquiry should be made, and if all these legal proceedings were to be duplicated and reduplicated at the expense of the manufacturer, it would go far towards putting a stop to manufacturers altogether. Clause 8 Mr. Cresswell had stated that he did not consider important, and if so, it ought to be taken out of the bill, for according to it, every individual who used a house drain, communicating with a river by the sewer belonging to the sanitary authority for the district, if such drain were a new one, would come within the meaning of the Act and be liable to a penalty of £50. The next matter he would consider was the standards set forth in the interpretation clause. In the first place he objected to the term *Standards of Purity*, as they were not standards of purity at all; the proper term as he understood it should be *Standards of Maximum Impurity*. Then again, the wording was open to objection when the standards were stated to be "any liquid" when the word *water* alone was intended; and throughout the standards given the term "any liquid," having "more than" a certain quantity of the different polluting matters, the words *more than* should be left out, otherwise they would not be standards. In his (Mr. Johnson's) opinion at the present time some of the standards were not possible to be attained to by manufacturers in certain places, and on the other hand those referring to acidity and alkalinity were far in excess of anything which ought to be permitted in any stream employed subsequently as a source of water supply, or even in the interests of manufacturers lower down the stream. That in making standards of maximum impurity some principles should underlie the standards applicable to certain sections of a river, such as the use of the water subsequently for town water supply; and it would be manifestly a hardship on manufacturers, and quite unnecessary, that those whose works are situated on the tidal estuaries of rivers should be governed by the same standards, although the water, from contamination with sea water, never could be employed as a potable water; for instance, it would be monstrously unjust to impose the same set of standards on the tidal portion of the Thames below Teddington Lock, as ought to be insisted upon above it in the interests of the water supply of the Metropolis. He was of opinion that different standards should be arranged according to the particular requirements of the case: thus, he thought that if *all the solids* from sewage or otherwise were prevented in the tidal estuary of the Thames, it would remove the great cause of complaint which has called forth the late Royal Commission which has pronounced that portion of the river seriously polluted. He thought it would be far better if the onus of taking proceedings lay in the hands of the sanitary authority. It was worded all through "any liquid," but it was not clear whether it meant any liquid put into the river, or the water of the river after it was put in. Then, again, it said continually "any liquid which contained more than one part by weight," etc., but if it were more than one part it could not be a standard. Again, he thought it was putting a standard of maximum impurity on the shoulders of manufacturers which they would never be able to

keep up to. If the bill was to be operative, the standards must be such that manufacturers could comply with them. He did not include the clause relating to arsenic, which he thought should be kept out entirely, but with regard to the question of acidity allowed to be put into a river, he had a great objection to such an immense amount as would be allowed. Clause *h* was any liquid possessing an acidity greater than that which is produced by adding two parts by weight of real muriatic acid to 1,000 parts of water. Now real muriatic acid was three times the strength of the strongest commercial fuming hydrochloric acid, and this would allow an acidity far too high. The same objection would apply to the case of caustic soda, which came in the next sentence. If standards were made, they ought to have some practical meaning. There should be standards of pollution, one for that portion of the river from which water was drawn, and the other for that which was polluted with sea water, or which might be called the tidal estuary of the river. Of course all solid matter ought to be kept out, and if that were done he did not think the rest would do much harm.

Mr. LUDWIG MOND said he had followed this question with attention for many years, and was greatly puzzled to know what the country and the Legislature were aiming at, and he failed to see it even now. The word "pollution" was nowhere defined. If it said that anyone should offend against the Act who poisoned a river or fouled it so as to be injurious to animal life, that would be intelligible, but this was not so. There was among the definitions at the end of the Act a standard of purity which went very much further, but he did not see where this was referred to in any of the other clauses.

Mr. CRESSWELL said it was in Clause 2.

Mr. LUDWIG MOND said if that was the only place, he took it that those who had hitherto spoken on the subject were entirely mistaken as to what the standard of purity meant. They did not refer to the liquor which left the works or went into any stream, but to the stream which was polluted. If it meant that the river was not to contain more than the standard allowed no one would object, and that was what he understood the Royal Commissioners on Rivers Pollution to mean.

Mr. CRESSWELL having read the last paragraph of Clause 2, said he would give an instance of what it was intended to prevent. A manufacturer poured the contents of his hydraulic mains into the Severn, and when indicted the defence set up was, if you analyze the River Severn half a mile below, you cannot find any trace of the pollution. It was monstrous to suppose that under such a defence a man should be allowed to pour the contents of a hydraulic main into a river; the intention of the Bill was that the stream poured into the river should be as pure as this standard, that if the stream contained a greater proportion of impurity than defined in A, B, C, or D you are open to complaint; on the other hand it is not a defence to say if you take the river water, and examine it after the waste liquid has flowed into it, it is less impure than any of those standards.

Mr. C. C. HUTCHINSON thought that it behoved them to ascertain that the machinery of any measure which proposed to deal with the subject should be of such a nature as not to prejudice manufacturing interests. He did not consider the bill before them of such a nature, and taking it altogether it was of a most rigid and unyielding character. He was unable to understand Clause 2, for it appeared to him that if an act of itself did not cause pollution a succession of such acts could not either. It seemed, however, that what was enacted was that although pollution might not be caused by any single material or person,

if two materials discharged into the stream separately, and by the same or different individuals, together produced a condition of things covered by one of the proposed standards of purity, such would be an offence, although taken separately no one of the acts contributing to the result infringed. This in many instances could be shown to be absurd. It was a pity that whilst they were drawing so largely in this bill upon the reports and recommendations of the Royal Commissioners on the pollution of rivers they neglected what was more valuable, in his opinion, than the enforcement of a set of arbitrary standards; he referred to the establishment of a Rivers Conservancy Board. This plan was proposed by Dr. Frankland and Mr. Chalmers Morton: it was infinitely more acceptable than the proposal made in the Act before them. This proposal virtually gave local boards and sanitary authorities the custody of streams, and, just as if they had not already more than enough to do, were constituted rivers conservators. He would ask those who had more experience of the working of local boards how such a measure would affect them. It had been pointed out by previous speakers that such boards would be the chief offenders, and would therefore be slow to put into operation a law which would recoil most powerfully upon themselves; that in itself was sufficient evidence of the impracticability of the proposed means of enforcement. Then, again, did they think that there were individuals sufficiently courageous to risk the costs of a lawsuit in order to compel an authority to exercise its functions; recent decisions in parallel cases, and the glorious uncertainty with which they seemed to be attended would deter any sensible person from embarking upon such a course, and, therefore, this Act would be just as much permissive, and would fail just as much as the Act in existence had failed. A central Conservancy Board would have none of these objections, because their sole functions would be to conserve the purity of the streams, and such an authority would discharge its duties both more efficiently and with more satisfaction to manufacturers, because they would have the guarantee that they had to deal with specific individuals and regulations, and would not be at the mercy of local boards, or the caprice of meddling individuals. Many of the standards of purity he thought so unreasonable as to be quite out of the question, *e.g.*, the proposition with regard to subsidence; that was perfectly unnecessary, for what did it matter how long a time was given so long as the other conditions were satisfied? With respect to the quantity of organic matter in solution, the effect of this standard would be to close at once nine out of every ten sewage works in the country, which were already satisfying the requirements of the Local Government Boards, for hardly one of them came up to the standard. The able report to which he had before referred shows that as far as sewage was concerned, the best chemical processes only removed from 28 to 50 per cent. of the organic carbon, and as sewage contained about 4.6 parts of organic carbon in 100,000 parts there would be still a quantity left behind which would considerably exceed that permitted by the Act. Again, the organic nitrogen in sewage equals about 2.25 parts per 100,000, and as the best chemical processes removed only from 36 to 65 per cent., as far as this was concerned the purification would not be nearly sufficient. It had been shown that so high results could only be obtained by intermittent filtration through prepared soil, and even then the results were not so concurrent as to comply continually with the Act: taking, however, that the best results of land treatment would be effectual, what were those manufacturers to do whose works

were so situated that land could not be obtained? They had in many instances been so built round that there was hardly a foot of ground available; how then, if this Bill became law, could they adopt the means which was the only one enabling compliance with its conditions; they could not make use of the sewers or the rivers for getting rid of their waste waters, and, as a consequence, the effect would be that such factories would have to be closed. No provision seems to have been made for the part of a river or the position of a factory, and whether it was necessary as far as the river was concerned or not, all were to be compelled to purify up to the same high standard. Then, again, there was no elasticity in the matter, no provision made for exceptional occurrences which were entirely beyond control, *e.g.*, the overflow of storm waters from sewers, such exceptions had been pointed out as desirable by the Royal Commissioners when conditions similar to the one referred to would arise, when polluted materials could not possibly be dealt with, and must at such times be allowed to pass into the river. In conclusion, he had to say that in his opinion a measure so inelastic, so rigid, and so harsh, hardly appeared a fit one to inscribe upon the statute books, and its rigidity was of such a character as to defeat its own ends.

Mr. G. BISCHOF: With regard to certain clauses:—

I. 2 (*b*). appeared practically to exclude all liquids which at any time have been contaminated by sewage matter, as no process is known by which every trace of such matter can be abstracted. If my view be correct, very few liquids remain which are not objected to.

II. 8. should have been made quite clear, whether or not the penalty of £50 is to be for each day from the date of the first conviction.

III. 9 (*a*). We have no method for accurately determining organic matter in a water residue. This might be attempted in a rough and unreliable way by incineration, or more accurately by determining the constituents of organic matter. It should therefore be clearly stated what is meant by "dry organic matter."

The first three lines of this clause appear to exclude, without exception, any liquid which has not been subjected to rest for a period of at least six hours. If this be intended unreasonably—for what is the use of subsidence if a liquid should contain no matter in suspension?—the last six lines from "or which not" are futile, as these seem to indicate that liquids of a certain purity may pass without having been subjected to such subsidence.

IV. 9 (*b*). What is understood by "real" muriatic acid?

Dr. PERCY FRANKLAND said that he should like to make a few remarks concerning the standards of purity which had been so severely criticised by the previous speakers. He did not intend to defend them in this place, but he wished to point out some serious errors which had been made in reference to them. The great majority of the rivers in the country would uniformly comply with these standards, and even such polluted streams as the Irwell and the tidal Thames were frequently within the mark. Thus, from a large number of analyses which he had made of the tidal waters of the Thames, he could state that the suspended organic matter was generally under two parts per 100,000. No doubt it would be preferable if some elasticity could be given to these standards, for it was a very different thing to pour polluting matter into a river near its source, and to pour the same matter into the tidal portion of the stream; and again, the volume of the river should be taken into account. The clause relating to petroleum had

been introduced into the standards on account of the prejudicial influence exercised by this material in preventing the purification of foul liquids containing only a minute trace of it.

Mr. CRESSWELL, in reply, said he must admit that many of the criticisms on this bill were well deserved; but the object of bringing it before the Society was that its faults might be discovered and amended. With regard to the first paragraph, Dr. Percy Frankland had already pointed out that subsidence was not invariably required; but questions of grammar were of minor importance compared with that of the standards themselves. He had always understood that they were standards with which every manufacturer, if he would, might comply easily; they were certainly standards with which the upland waters of nearly every river in England complied. As the Society included some able men who were members of Parliament, it was certain that this question would not pass through committee without being properly ventilated. Mr. Johnson had spoken of a separate standard for each river. He recollected that Mr. Crookes, at the Hygienic Council, at Brussels, promulgated an idea which, at the time, much fascinated him, viz., that to lay down absolute standards of purity for all and every river was a mistake. Every river in the country had its own standard. If it were to be enacted that no one should be permitted to pass sewage or any other matter into it less pure than the river itself at the point of inflow, beginning from the head of the stream down to the sea, in the course of a very few years the river would become comparatively pure throughout its course. If the miller at the head of the stream were bound to comply with that provision, he would have his standard in the purity of the water from the rock. Below him would be the native purity of the rock plus A's, pollution, C would have A plus B, and so on, and as it were by a process of induction, you would eventually arrive at a pure stream. It would be ridiculous to impose a standard for the Thames at Gravesend such as was required but not yet acquired at Staines. He thought it would be better to expunge the whole of the standards, and enact that no person should be permitted to pass into any stream, whether through an old or new channel, anything which was less pure than the river itself at the point of junction. It would be a gradual process, and could only be done gradually. With respect to Clause 5, he was disposed to agree with Mr. Johnson that such a provision would not be entertained for a moment. Attention, however, had not been called to the fact that the complainant was bound to give security for costs, and would have to do in this as in every other case, take the burden of the law, and all its responsibilities, on his own shoulders; otherwise you cannot appeal to justice. Clause 8 seemed to have caused some amount of amusement, but on reading the first three lines the clause was as simple as possible. It was said by a species of the house-that-Jack-built-argument—"if you open a channel into a drain that opens into the sewer, and that sewer opens into the river, you are practically opening a new channel into the river. The object of this Act was to prevent house drains or sewers from being connected with any river. If drains and sewers were cut off from the rivers the new channels might open into the sewers, and the contents would go on to the land or into tanks where, by subsidence or precipitation, you could obtain an effluent fit for tidal streams, and, if required, where you could complement the process by deposition or filtration through prepared soil. The effluent would never enter the river at all until it was comparatively purified. He had heard it said by an eminent authority that if manu-

facturers would listen to the advice of their engineers and chemists it would be possible for them all to deal with their pollution, not only without loss and inconvenience, but in the majority of cases with profit to themselves. There were manufacturing processes which had been used for years, of which it had always been said that it was impossible to carry them on without polluting the rivers. Many in north and south earnestly believed that the manufacturing industries of this country involved in some measure the pollution of its rivers; and to them he would say that this bill had not assumed a definitive shape; there was elasticity in it as in any other bill before Parliament. If they would only bring the same acumen to bear upon it in committee as in that room, without doubt it would come out from the crucible a better bill than it was at present. With regard to the question raised by Mr. Hutchinson, that to place the conservancy of rivers into the hands of local boards was preposterous inasmuch as they had already much to do which they refused to do, he quite agreed with him. These boards were often composed of men who had learnt but one art in this world, viz., the art of doing nothing. In the conference, to which he had previously alluded, at the Society of Arts, he had brought forward a resolution which was unanimously adopted by a crowded meeting of surveyors, officers of health, etc., etc., in favour of the constitution of county boards, and after specifying several matters which should come under their control, concluded as follows: "That such county boards should be charged with the conservancy of rivers, including the prevention of floods, the storage of water, and the preservation of rivers from pollution."

The CHAIRMAN having proposed a vote of thanks to Mr. Cresswell for his exposition of the Bill, moved—"That this meeting of the London Section of the Society of Chemical Industry, being of opinion that the proposed 'Rivers Pollution Bill' is inadequate to the objects of its promoters, and injurious to the interests of manufacturers, recommends its early consideration by the Council of the Society, with a view to such action on its part as the interests of industrial chemistry may require."

Mr. TYLER seconded the motion, which was unanimously agreed to.

## THE HYDRATION OF CELLULOSE.

BY C. F. CROSS AND E. J. BEVAN.

In the historical development of chemical theory it frequently happens that doctrines are eclipsed or temporarily overthrown by the revelation of new groups of phenomena, with which, while at first sight they seem incompatible even to contradiction, they ultimately come to be reconciled, though not perhaps without modification. Thus, the term carbohydrate, given by chemists of a former generation to the group of compounds comprising the sugars and starches, implies an interpretation of their general empirical formula  $C_nH_{2(n-m)}O_{n-m}$ , which is now recognized to be crude as\* it has been misleading. It would be impossible in the light of modern views to regard these compounds as hydrates of carbon in the more particular sense of the term; on

\* We have seen in a modern text book the decomposition of sugar by sulphuric acid stated to be a resolution of its molecule into carbon and water, and advanced consequently as an evidence of the fitness of the term.

the other hand it has been lucidly shown by Baeyer,\* in gathering up and more precisely expressing the latent views of chemists upon the peculiar relationships of this group, that they are susceptible of such profound and varied modifications by the loss and resumption of water molecules, *i.e.*, by dehydration and rehydration, and in this respect are so much more active than any other group of carbon compounds, that they are the hydrates of organic chemistry, *par excellence*. Certain of these transformations had been long known, as their nature had been empirically recognized; but to Baeyer belongs the merit of applying to their investigation the various types of hydration changes which have been established for the simpler and better known carbon compounds, more particularly of showing that upon such a basis the phenomena of the fermentation of the sugars admit of consequent and consistent chemical explanation. It is well known that this was a favourite tenet of Liebig's, and that his last researches were directed to its establishment in opposition to the teachings of Pasteur; his experiments and conclusions, however, suffered eclipse in the vast accession to our knowledge of the biological side of the phenomena, which came from the study of organized ferments. Now, however, that we see reason for regarding these as affording rather the exciting and directing than the sustaining cause of the molecular resolutions,—these resolutions being, moreover, as has long been recognized, not different in kind from those determined by what we may call purely chemical causes,—Liebig's experiments and his conclusions, modified by Baeyer's wider interpretations, may be re-introduced and allowed their full weight in the development of a chemical theory of fermentation. Into this controversy, however, we have no authority nor desire to enter; our object in this communication is to point out the bearings of the study of hydration changes upon certain of the many unexplained transformations of the celluloses. In the treatise cited above, Baeyer does not extend his discussion to the more complicated carbohydrates; and if we make the attempt to apply his conclusions to the better understanding of the hydration changes of the celluloses and the bodies allied to them, it can only be, we need scarcely say, in a very general way, with a clear recognition of the exceptionally complicated nature of the problems involved, and of our inability to do more than suggest a factor in their solution, which has hitherto been neglected.

It has, of course, long been recognized that hydration changes play a prominent part in the elaboration of cellulosic tissues; and apart from the more obvious dehydration which attends the transition from the plastic organization of actively growing parts to the condition of solidified tissues, it is certain that hydration changes of the more recondite order, probably also of a character even more elaborate than those which Baeyer has formulated, contribute largely to the result.

With regard to the former. It has doubtless struck every observer who has made a proximate analysis of a living or once living vegetable tissue, that the line of cellulose, as of lignose or woody fibre, has to be drawn in a very arbitrary manner; that in addition to the insoluble product which survives a succession of alternate treatments with a halogen or an acid, and alkaline solutions, there are present in the tissue a number of bodies of similar characteristics which disappear in course of the treatment as soluble derivatives. Many of these compounds come to be grouped together and dismissed under such terms as "extractive matters," which sufficiently indicate the

empirical nature of the processes by which they are estimated. It is certainly a matter of great difficulty to determine the precise characteristics of such groups of compounds, as it is, therefore, to deal with them in our processes of analysis upon a more rational system. As a first guide to work in this direction, we may assume the existence of series of carbohydrates differentiated in point of hydration; and, therefore, of the presence in a growing tissue of transitional links of the chain connecting the celluloses with the simpler carbohydrates. These bodies are probably celluloses in every respect but the "condensation," which characterizes the insoluble and better known forms. In the course of certain investigations which we had the pleasure of conducting for Sir J. B. Lawes and Dr. J. H. Gilbert, we had ample opportunity of confirming these views by experimental verification. Adopting the hydration hypothesis, we tried the effect of the simplest process of dehydration of the tissue, *viz.*, exposure to the action of alcohol at ordinary temperatures for some days.† The effect of this upon the cellulose of the tissue was manifested, though, of course, but imperfectly, by the increased yield of insoluble cellulose, resulting from the ordinary method of isolation: alternate treatment with chlorine and weak alkaline solutions. This is shown by the following numbers:—

(A) Samples of mixed herbage from grass land, made into hay. Cellulose percentage—

	(a) Isolated directly.	(b) Isolated after Alcohol treatment.	Difference.
Specimen (a) .....	31.4	34.6	3.2
" (b) 1 crop 21.3 .....	27.1	27.1	2.8
" (b) 2 .. 50.0 .....	51.6	51.6	1.8
" (c) 1 .. 21.5 .....	24.7	24.7	5.2
" (c) 2 .. 23.3 .....	27.0	27.0	3.7

(B) Specimens of growing (green) crops, treated immediately after cutting—

	(a) Directly.	(b) After Alcohol treatment.	Difference.
Triticum pungens .. 21.7 .....	26.1	26.1	4.7
Oats, Leaves .. 28.2 .....	35.1	35.1	7.2
" Stems .. 29.5 .....	34.5	34.5	5.0
Clover Stems .. 21.0 .....	29.5	29.5	5.5

The treatment with alcohol consisted in leaving the specimens in contact with strong spirit for 14 days, fresh alcohol being substituted once or twice.

We have made similar determinations in specimens of ensilage, which we had the opportunity of investigating for Mr. G. Fry, and with similar results. Thus, in a sample of grass silage we obtained as the mean of two concordant determinations, 34.2 per cent. cellulose by direct experiment; 44 per cent. after treatment with alcohol. These numbers and results need confirmation and extension by further investigation, for which at least they indicate a useful direction. The value of cellulose and lignose as food stuffs to the herbivora has been a subject of considerable controversy. Should it be proved that the substances to which these terms are applied are simply members of series which graduate into soluble carbohydrates, their digestibility or otherwise will be shown to be bound up with their condition of hydration. Certainly the subject is worthy of the attention of all those who are engaged in investigating the food value of agricultural produce, and the influence upon it of the various methods of storage and preparation.

The fully elaborated celluloses, on the other hand, such as the isolated plant fibres in the condition in which they are applied to their various uses in the arts, necessarily require a more severe treatment to

\* Ueber die Wasser-Entziehung und ihre Bedeutung für das Pflanzenleben und die Gährung. Berl. Ber. 363 (1870).

† Mere drying is attended with similar results. H. Müller (Unpublished Observations). Cf. Jour. Chem. Soc. Jan. 1885. p. 51.

bring about hydration changes. The investigation of these changes is not merely of technological interest, but must also contribute to the solution of the problems of the chemical constitution of their constituents. Assuming that in these transformations all the well-known types of hydration are represented as well perhaps as others not yet investigated, we may proceed to inquire into the degree of conformity of experience with this as compared with other explanations which have been advanced.

\* It is especially important to bear in mind in this enquiry two of the known types of hydration which are perhaps the most remarkable, viz.: (1) That which without altering the number or kind of atoms in a molecule effects their rearrangement as the result of dehydration followed by a rehydration which, taking a different course from that which the dehydration might be supposed to prepare for it, produces therefore an isomeride of the original. (2) That which, being of the same character as (1), effects a resolution of the molecule, the sum of atoms remaining unchanged. These changes may be simple or multiple. In the latter case resolution frequently results from the accumulation of oxygen by successive migrations to a centre within the molecule. It must be also remembered that these changes consisting of a series of dehydrations and rehydrations, with their attendant rearrangements and resolutions, may take place simultaneously in a system of similar molecules—the surrounding physical conditions remaining unchanged.

The consideration of these probable factors of the transformations of cellulose reveals, and at the same time in some measure defines, the complications of the problems which they present.

Some of these we may now proceed to consider, taking first the typical or cotton cellulose. This cellulose is extremely inert, and requires comparatively severe treatment to bring about transformations involving the exchange of water molecules. With regard to the simplest determining cause—heat—the recent experiments of Scheurer and Grossetest† have proved that the effect of heat upon the fibre becomes suddenly marked at 160°, whether heated in dry air or in contact with water, which point, therefore, is regarded by these observers as the "critical" temperature of dehydration of cotton cellulose. The action is suddenly marked in point of temperature only, not in regard to time; it required a lengthened exposure to this temperature to bring about the structural disintegration adopted by these authors as the measure of molecular change, and exposure to the temperature of 150° for the same period effected no appreciable change. The identity of the results obtained in air and water eliminates the influence of oxygen as a factor of the molecular change, and reduces it to one of simple dehydration. The most obvious feature of the transformation is as before observed the structural disintegration of the fibre; this result we may provisionally regard as a criterion of dehydration, proceeding to confirm its adoption by the investigation of other instances of action which, reasoning from all analogy, are dehydrating. Concentrated hydrochloric acid rapidly disintegrates cotton when placed in contact with it at ordinary temperatures: the greater portion is converted into a friable modification having properties which identify it with Girard's hydrocellulose‡, at the same time a portion is converted into soluble derivatives of the dextrin type. The difference

between the weight of the insoluble product and the original cellulose we have found to be 7-10 per cent. The formula which Girard assigns to hydrocellulose is  $2C_6H_{10}O_5 \cdot H_2O$ , and he supposes it to be formed from cellulose by a process of hydration. On the other hand, the conditions under which he states that it is formed—he particularizes exposure to sulphuric acid of 45° B. in the cold, or to boiling dilute acids—are of a dehydrating or condensing tendency; and further, such a hydration of the cellulose molecule remaining otherwise intact involves a gain in weight of some 5 per cent.; whereas, we have, in the case in question, always observed a loss. The only consistent inference from these facts is that the production of a cellulose hydrate under the circumstances and conditions we have described, is preceded by a dehydration and condensation of the cellulose; that the hydration therefore is not of a simple character, but results from a molecular rearrangement. The doubts which have been cast upon Girard's interpretations of the phenomenon§ show first, the necessity of a clearer appreciation of the possible complications of cellulose hydration, and secondly, the importance of carrying out all investigations of the transformations of cellulose on the basis of a strictly statistical study. The action of sulphuric acid in its more concentrated forms is to resolve the cellulose in various ways, according to the duration of contact: parchment paper, amyloid and dextrin, represent the products corresponding with varying durations. As all these products are obtained only after a subsequent dilution of the acid, it has never been shown what is the condition of the products of the original action of the acid. The concentrated acid might be supposed to combine with the cellulosic C-methyl after the manner of its combination with aromatic groups, acting, i.e., as  $SO_3H.OH$ , forming sulphonated compounds of little stability, which are decomposed by water and simultaneously hydrated. Such a reaction would involve an oxidation of the carbon nucleus, and of this it would be as difficult to bring direct proof as it would be to show that the hydrated monoxide of a dyad metal is correctly written  $M \begin{smallmatrix} OH \\ \diagdown \\ OH \end{smallmatrix}$ . Indirectly, we have

evidence of the disturbance of the oxygen equilibrium of the cellulose in the presence in the insoluble product (parchment paper) of active aldehydic groups, such as cause it to react with phenyl hydrazine, to reduce Fehling's solution, and to behave much in the same way towards reagents as Witz's oxidised cotton (*loc. cit.*), and also in regard to the increased manifestation of these properties with age.

It is worthy of mention here, that the reaction of sulphuric acid on heating with the pseudo carbons, by which these are oxidised and sulphurous acid evolved, is a reaction of the acid with condensed cellulosic derivatives, the occurrence of which increases the probability of its taking place as a transitional phase of the reaction with other members of the cellulosic series, and under less extreme conditions.

The subject is one that requires revision, and we are engaged in the reinvestigation of several points here touched upon.

The action of alkaline solutions upon cotton is very slight unless they are applied in a concentrated form, or the temperature be raised very much above the boiling point. Under these circumstances the cellulose undergoes a modification which is, as regards physical properties, the very antithesis of the disintegration produced by acids, the products having a gelatinous character resembling the colloidal hydrates of the inorganic oxides. This hydration of the

\* For the full discussion of these Hydration Types, *vide* Bayer's original paper or the translation by Dr. Armstrong, in the Jour. Chem. Soc. [19, 331.

cellulose appears to be of the simplest character and, provided oxidising influences are excluded, to be unattended by any resolution of the cellulose molecule. The dissolution of the cellulose by the Schweitzer reagent we may regard as an extreme case of such hydration. It has not been attempted to decide what is the particular relationship of the ammonio-hydroxide to the cellulose molecule which may be regarded as the determining cause of the reaction; suffice it for this discussion to recall the evidence of its simplicity, viz., the ease with which the cellulose may be recovered, the completeness of the recovery, and the identity in regard to chemical properties of the reprecipitated with the original cellulose.

We pass on to consider the question of the hydration changes of cellulose produced by the action of dilute acid and alkaline solutions with the condition of oxidation super-added. Of the former we may instance nitric acid. In studying the reaction of cellulose with the dilute acid (60 per cent.) at 80° to 100°, we distinguished a preliminary stage in which the cotton was disintegrated (converted into hydro-cellulose?), followed by the oxidising action, the course of which was evidenced by the nitrous fumes in the vessel; this oxidation was a very gradual process at the temperature and with the concentration of acid employed; lastly, we observed the well-marked combination of the insoluble product, oxycellulose ( $\beta$ ), with water on subsequently washing. We further observed in the statistical study of the decomposition that it proceeded to a limit which was reached when from 60 to 70 per cent. of the cellulose had been oxidised away. The most characteristic features of this decomposition are the absence of intermediate products, the comparatively small differences in composition of the cellulose oxyderivative  $\text{NoC}_{15}\text{H}_{26}\text{O}_{15}$  (C 43.4; H 5.2) from the original cellulose  $\text{NoC}_{15}\text{H}_{30}\text{O}_{15}$  (C 44.1; H 6.1), their general similarity in properties but particular differences in regard to capability of colloid hydration and of being attacked by dilute nitric acid. Reviewing these facts we infer that the primary action of the acid, which is oxyhydrolytic, is complicated because antagonised by subsidiary results in which the peculiar characteristics of the cellulose molecule in relation to hydration are manifested; and that the cellulosic product is the resultant of the dehydrating and hydrolytic actions which are brought into play. It should also be borne in mind that a mass of cellulose is not to be regarded as homogeneous, but as the researches of Crum have shown,\* chemically as well as structurally differentiated, the variations brought to light being moreover of such a kind as are consistently explained by reference to hydration changes. Such differences obviously influence more particularly the relationship of the cellulose to hydrolytic agents, and are doubtless operative in the decomposition in question.

The oxidation of cellulose in presence of alkalis is of a progressive nature, giving rise to an extended series of intermediate compounds. The products of the action of an alkaline solution of permanganate are acid bodies having the characteristics of the pectic group. We obtained as a first limit of the decomposition, i.e., when all the cellulose (employed in the form of the gelatinous hydrate reprecipitated from the Schweitzer solution) had disappeared in solution, a highly acid body or mixture of bodies having the empirical composition  $\text{C}_{19}\text{H}_{17}\text{O}_{22}$  (C=38.1, H=3.1) very hygroscopic and reducing Fehling's solution on gently warming.†

‡H Müller obtained products which appear from

his description to be of a similar nature, by the action of strong solutions of the hypochlorites upon cellulose. The series of oxidised derivatives of cellulose described by Witz in his recent interesting memoirs‡ are obtained for the most part by oxidation under the condition of a feebly basic or acid reaction, and influences which in themselves are not usually productive of hydration changes. That such take place, however, as a consequence of the oxidation, we infer from the structural disintegration of the fibre. This is immediate if the oxidation be severe, but under less extreme conditions the oxidation appears rather to open up a path for oxyhydration changes which proceed after the removal of the cellulose from the oxidising influence. The inference as to the occurrence of such hydration changes is necessary to account for the profound modification of the fibre, and the marked increase in the chemical activity of the cellulose product, which accompanies a scarcely appreciable change in empirical, i.e., aggregate composition. The chief feature of these oxy-celluloses (α) is the presence of active acid and aldehydic groups, and they occupy a position intermediate between the series of compounds described above, corresponding indeed with the conditions of their formation.

If we turn now from cotton cellulose to other substances of similar composition to which the term has been applied, and chiefly to those forms which are more familiar to us by reason of their technological applications, we find that they differ from the former or typical cellulose in chemical as well as morphological characteristics. So far as they have been investigated these differences do not appear of much moment in comparison with the broader features of resemblance, but they may be taken as indications of greater differences which future research will doubtless bring to light. We have frequently alluded to the celluloses isolated from lignified tissues by processes of chemical resolution, and to the fact that they more nearly resemble in composition and properties the oxycelluloses. The greater activity of these celluloses is seen in their affinities for colouring matters, in their reduction of cupric oxide (Fehling's solution) and in their reactions with the aromatic bases. Of these we have found phenylhydrazine\* especially useful in revealing differences which might otherwise be overlooked; celluloses when boiled with an aqueous solution of its salts are coloured more or less deeply (yellow) in proportion to their synthetic activity. A solution of aniline sulphate at the boiling temperature, gives a very striking reaction with certain celluloses, notably those isolated from esparto and straw by the ordinary process of digesting with a solution of caustic soda at an elevated temperature. These are dyed a rose-pink of varying intensity, a reaction which we have found useful in detecting their presence in white paper.

Celluloses which are isolated from combination by means of processes of hydrolysis, are doubtless themselves modified by hydration changes induced by the conditions under which they are separated, and the reactions in question may result from modifications in constitution, i.e. partial resolution, which accompany these changes. So little however do we know of these compounds, that we cannot do more than adopt the suggestions of these observations as a guide to future investigations.

A distinctive feature of these various celluloses, which is referable to their varying capacities for colloid hydration is the varying degree of softness

and elasticity which they possess after drying from the moist state by the aid of heat\*. The fibrous celluloses of the arts in their normal state are not susceptible of such changes as affect these properties, except under severe treatment, but when imperfectly elaborated these celluloses, as others in their normal condition, are very easily converted into hydrated gelatinous modifications, notably under the action of alkaline solutions. The presence of such hydrates and their effect upon a cellulose fibre is demonstrated by a comparative treatment with alcohol previously to drying, this method of dehydration preventing in a great measure the peculiar aggregation of the fibres which otherwise attends the drying from water. The conversion of cellulose into such hydrates is to be regarded technologically as a degradation, and it will be found that the commercial value of a cellulose is *ceteris paribus*, in the inverse ratio of its tendencies in this direction. The influence of alcohol upon celluloses of this character has been dealt with in the earlier part of this paper, and from the results there detailed we may infer that their conversion into soluble derivatives by the action of alkaline solutions is correlated with the tendency to colloidal hydration, which we may regard as a transitional stage. These points are of especial technical importance at a time when so many new processes for the preparation of cellulose are claiming the attention of manufacturers, and a careful consideration of their bearings will enable us to form a better appreciation of both processes and products, than on the assumption that a given raw material will yield the same cellulose whatever the process by which it is isolated.

We pass on to a brief consideration of these processes in relation to the general question of the hydration of the celluloses. As a necessary preliminary we devote a short space to the examination of the raw material (for the most part lignified cellulose or lignose) from the point of view from which we have discussed the celluloses. We have already shown that the action of hydrolytic agents upon the compound celluloses of the lignose class is, in the first instance, to resolve them partially into soluble derivatives which retain all the essential chemical features of the original. To illustrate this point afresh we may cite some recent experimental results.

A specimen of jute was boiled 12 hours with dilute sulphuric acid (7%), a stream of  $\text{SO}_2$  being continuously passed through the boiling solution. The insoluble residue was a brownish red powder, the fibre having undergone complete disintegration, and when dried and weighed was found to amount to 64 per cent. of the original fibre. A comparison in regard to chemical composition gave the following results:—

	Residue.	Original fibre.
Carbon percentage.....	47.5	47.3
Cellulose isolated by (Clevland).....	75.0	76.5
Carbon percentage of cellulose.....	43.3	45.5

Notwithstanding, therefore, that a large proportion of the fibre constituents yielded to the hydrolytic action of the acids, becoming converted into soluble modifications, there had been no sensible change in composition. This result confirms many that we had previously obtained; in this case, however, the hydrolysis had proceeded farther in consequence of being aided by the sulphurous acid, and the result is therefore the more striking. In this hydrolysis a considerable quantity of furfural is liberated. We have endeavoured to determine the quantity formed by taking advantage of its colour reaction with aniline salts.† In this case we employed hydrochloric

acid only, diluted with twice its volume of water. The quantity estimated was 11 per cent. of the weight of the fibre; with hydrochloric acid of 10 per cent. the quantity was 7.5 per cent., and with sulphuric acid of 10 per cent. 11.2 per cent. of the fibre.‡ The stony concretions of pears, Erdmann's glycedrodipose which we have shown to have a similar constitution, yielded under the same treatment a quantity of the aldehyde estimated at 18.6 per cent. of the original substance. It is unnecessary to say that these numbers are to be regarded only as approximations.

It is these hydration changes of lignose and its allies which in our estimation, throw doubt upon the "merustation" theory of lignification. The incrustation of fibres is of course on the one hand, a morphological fact, but to account for it by a chemical incrustation, is a pure hypothesis resting upon an equally hypothetical analogy. As we have frequently pointed out, the reactions of the jute fibre (bastose) are not those of a crude admixture of a cellulose, as usually understood, with non-cellulose constituents which, while imparting to it its peculiar features of difference from a simple cellulose fibre, overlie it in such a way as to mask its reactions; but are of such a nature as to indicate that it is at least chemically homogeneous, in the same sense that the true celluloses are taken to be. Such a theory of the constitution of bastose does not exclude any more than in the case of the celluloses themselves, the differentiation in point of hydration which undoubtedly marks the natural fibre; indeed its relations to the question of hydration, as here discussed, present the closest similarity to those of the simple celluloses, of which they are in many respects typical. The hydration changes determined by reagents are similar in that they do not affect the essential chemical features of the original; but under conditions which disturb the balance of oxidation of the molecule, a fundamental resolution occurs, into products which are derivatives of the constituents of the original fibre, and from which, making due allowance for the changes accompanying the resolution, we may infer its probable constitution. So we take bastose and its allies to be compound celluloses, resembling the simpler celluloses to the extent that such a qualification implies. Whether, or rather, in what way genetically connected is a problem for future solution, to which the investigation of hydration changes may be expected to contribute.

We may now turn to a brief consideration of the processes by which these lignocelluloses are treated for the isolation of a paper-maker's cellulose. Having regard to our present point of view we shall treat them in the order of the temperature they employ as the condition the most obviously affecting the hydration changes.

(1) *Temperature below 100°*.—There is only one such process at present known, which is practically available, and that is the treatment with a concentrated sulphurous acid in closed vessels, at 80° to 90°, and at the corresponding pressures§ ( $\text{SO}_2$  of 4 to 5 atm. From the study of this process with the kind assistance of the inventor, we conclude that the action of the acid is purely hydrolytic; this is to be inferred from the examination of the products and from the perfect recovery of the sulphurous acid after the treatment. In regard to the intermediate stages it is highly probable that the acid fulfils a second function, and that its hydrolytic action is so much more complete than that of other aqueous acids by reason of its promoting oxygen-exchanges, and consequent re-arrangements. In its last results, however, these

\* J. Chem. Soc., Jan. 1883.

† V. Meyer, Berl. Ber. II, 1870.

§ Patented by Raoul Pietet. German Pat. 1833, 26,331; cf. Eng. Pat. 2,921, 1866.

probable changes do not appear, and having regard to these, its action is one of the simplest hydrolysis. The resolution of the lignocelluloses by dilute nitric acid at 60° to 80° is apparently simpler, but the hydration and other changes involved are in reality much more complicated, as may be inferred from the products and from the oxidation which accompanies their separation. The same considerations apply to Schulze's method of isolating cellulose by prolonged digestion of these lignocelluloses at still lower temperatures with dilute nitric acid, with addition of potassium chlorate. Both these oxyhydrolytic processes are, however, rather of laboratory than technical interest; and of less theoretical interest than the sulphurous acid process, because more complicated. This latter is then the simplest case of the hydrolytic resolution of a lignocellulose into an insoluble cellulose, and soluble derivatives of the so-called encrusting substances. As already explained, those reagents which are hydrolytic only, *i.e.*, which are incapable of determining oxygen exchanges, do not resolve these compounds, but rather dissolve in virtue of hydration changes.

(b) *Temperatures above 100°.*—The lignocelluloses, as indeed the celluloses themselves, are considerably attacked by exposure to water at 160 to 170°. The reaction we may suppose in the first instance to be one of dehydration, but the products of the consequent resolution having a hydrolytic action, this new and opposite condition is introduced, and the brown coloured disintegrated product may be regarded as the resultant of these actions. The introduction of certain normal but unstable salts for the purpose of combining with the soluble products of resolution, simplifies the decomposition, and allowing it at the same time to proceed much farther the resolution of the lignocellulose is more complete. Of such salts the most important are the sulphites of the alkalis and alkaline earths. By the presence of these the additional complication which results from oxidation is likewise prevented. That their function is an indirect one, and that they do not materially contribute to the hydrolytic influences, is to be inferred from the fact that they do not affect the physical conditions necessary to be employed. As regards their mode of combination with the products, it is probable that they become split up into base and acid salts, the former going to the OH groups, the latter to the aldehyde products of resolution. Such a division corresponds to that of the most important processes of the paper-maker into (a) the older alkaline treatment and (b) the recently developed acid-sulphite processes. These we have contrasted and more fully discussed on previous occasions;\* here we may simply indicate their leading features in regard to the hydration changes involved. The temperature required for these resolutions is lower than for the preceding processes, and the cause is to be found in the additional hydrolytic action of the free alkali and acid respectively. The tendencies to a reversal of the hydrolysis by dehydration of the dissolved products are met in both cases by their combination with the reagent employed; the complications which result from oxidation are on the other hand prevented in the sulphite treatment, but intensified in the alkali processes, as the comparative study of the by-products of the two processes sufficiently shows. Of the differences between the isolated celluloses we have already spoken. Future investigation will establish these more clearly.

We trust that this brief and imperfect discussion of a complicated subject will contribute to the elucidation of the problems of cellulose chemistry.

## COMPOSITION AND MANURIAL VALUE OF FILTER PRESSED SEWAGE SLUDGE.

BY JOHN M. H. MUNRO, D.S.C., F.C.S.

(Professor of Chemistry in the College of Agriculture, Downton, Salisbury.)

THE application of the filter press to the treatment of sewage is, perhaps, the most important step that has been taken during the last few years towards the complete solution of this difficult problem. It is admitted on all hands that whatever changes may take place in the mode of collection and disposal of excreta in the near future, there will, for a long time, remain to be disposed of in nearly all our populous towns an enormous quantity of "sewage" similar to that which flows through the main sewers of the metropolitan area—human excreta, diluted to an almost worthless point with household waste water and with the storm water and road dirt conveyed into it by the street gutters. This material is so dilute, that irrigation, in one form or another, has seemed for a long time to offer the only chance of utilizing it with any prospect of profit. In a few instances irrigation has apparently had this desirable result, but in perhaps the majority of cases in which it has been tried it has proved more or less of a dismal failure. I think I may go as far as to say that the irrigation of ordinary arable land with crude sewage has never proved successful from the double point of view of avoiding a nuisance, and of disposing of the sewage at a commercial profit. There are, of course, several causes for this disappointing want of success, but the chief amongst them is the inability of arable soil to deal with a continuous supply of sewage without great deterioration in its purifying and aerating properties, so that at last it becomes "sewage sick," and inefficient as a purifying agent. This is not completely remedied by "intermittent" filtration or irrigation, for the land which has been often covered with crude sewage never recovers, even by rest, its original efficacy. The commonly accepted, and I believe the true explanation, of this is, that the slimy suspended matter of the sewage gradually chokes the pores of the soil, forming a deposit impervious to air, and thus preventing the aeration essential to nitrification, and on the other hand encouraging putrefactive fermentations. The removal of this suspended matter from the sewage, however, renders irrigation much more practicable; with a clear effluent and a porous soil the nitrifying power brought into play is enormous, and a moderate area of soil, whether grass land or arable, can deal with large and almost continuous doses of sewage water.

Nitrification, as has been shown by the experiments of Mr. Warington, and by my own (which were undertaken to confirm his results, and to extend them to the case of natural waters) is a process which varies enormously in rapidity according to the favourable or unfavourable nature of the conditions under which it takes place. It may proceed at an almost imperceptible rate for months, or it may be altogether in abeyance, when by a slight change in temperature, in the aeration or the reaction of the medium, or in other circumstances not fully ascertained, the process suddenly starts into vigorous activity, and completes its work in the course of a few days. Amongst the clogging or retarding conditions I find the absence of air and the presence of objectionable organic matter to be almost as important as a lowering of temperature. It will readily be understood then, that the removal of the suspended matter from sewage becomes equally desirable whether the effluent is to be used for irrigation, or is to be discharged in its partially purified condition into the nearest stream.

\* *J. Soc. Arts*, 31, 220. Reports (Essays) I. Forestry Exhibition, Edinburgh, 1884.

At Salisbury, for example, the sewage has hitherto been discharged in its crude state into the Avon, a river which has for a very long time been employed for the irrigation of the extensive water meadows which line its banks almost all the way from its source to the Hampshire coast. This river is about as favourably circumstanced as any in the kingdom for dealing with sewage directly discharged into it; and the extent of purification effected by the water meadows may be judged from the fact that a very short distance below the city there is no trace of sewage contamination in any form, and the water is perfectly pure, bright, wholesome and sparkling. Even here, however, the presence of the sludge is felt to be a difficulty, and the condition of the river having been objected to by the landowners immediately adjacent to the sewage outfall, it has been decided to precipitate the sludge by chemical means, to filter press it, and to discharge the purified effluent into the river as before. When this is done the water meadows below the city will still reap the benefit of the greater part of the fertilizing matter of the sewage, whilst no nuisance will be occasioned in the river even in the immediate vicinity of the sewage works. As regards other modes of dealing with the suspended matter of sewage, it is, I think, sufficient to remark that unless filter-pressed and quickly disposed of, sludge is even a greater nuisance when separated from sewage than when mixed with it. The slow drying up, for instance, of a deposit of wet sludge by simple exposure to the air is productive of nothing but odours of putrefaction, and the accumulation of a material concerning which people entertain but the sole desire to be as far away from it as possible.

Mr. C. C. Hutcheson, in a paper published in the February (1883) number of the Society's Journal, has given such a full description of the process of filter-pressing, and of the results obtained by its application to sewage sludge, that there is no need for me to enter into any detail on this part of the subject. The disposal of the filter-pressed sludge, however, is a matter which has not yet been brought to a successful issue, and as the number of towns and districts dealing with sewage by precipitation and filter-pressing is increasing rapidly, it becomes a question of great importance to find some means of utilizing the very large quantities of pressed sludge cake that are certain to be produced.

The sludge before pressing contains as much as 90 per cent. of water, and this is reduced by the filter-press in the course of a very short time to about 30 per cent., leaving the sludge in the form of compact circular cakes (somewhat resembling oil cakes) of brown or olive-green colour. The cakes in this condition contain 6 to 9 per cent. of nitrogen and over one per cent. of phosphoric acid, and should be of considerable manurial value. But no actual comparative trials of its value as a manure have, to my knowledge, been made, and in default of any recognised value conferred upon it by such means its sale at any price becomes a matter of difficulty.

In order to give, if possible, a definite agricultural value to the filter-pressed sludge, or at all events to obtain some knowledge of the conditions under which it may best be made available, I determined to make use of the facilities kindly afforded me by Professor Wrightson on the College of Agriculture Farm, to institute a series of comparative manuring trials of various samples of the sludge against farmyard manure and artificial fertilizers of known value.

By the kindness of Messrs. S. H. Johnson and Co., the filter-press manufacturers, of Stratford, I obtained, in February last, samples of sludge from three differ-

ently situated districts in which chemical precipitation of the sewage is combined with subsequent treatment of the precipitate in filter-presses. I received simultaneously half a ton of broken cakes of each sample, delivered in superphosphate bags of the usual size, and I will proceed to describe the appearance, mode of production, and composition of each sample, before detailing the arrangement and results of the experimental plots.

**Coventry Sludge.**—In this case the sewage of a manufacturing town is precipitated by the successive addition of sulphate of alumina, sulphate of iron, and milk of lime. As this treatment is succeeded by filtration of the effluent through land, and as the works are small compared with the quantity of material with which they have to deal, precipitation in the tanks is not so complete as it would otherwise be. The matter escaping collection in the tanks will be the lighter flocculent matter, and that requiring the addition of a larger quantity of the reagent for precipitation—in both cases rendering the precipitated sludge poorer in nitrogen. The town is a water-closeted one, although not altogether so, and the manufactures which have any effect on the sewage, are chiefly of the lighter textile kind, such as ribbons and tapes and other "Coventry" goods, thus contributing a fair amount of dyeing refuse. There is no "separate system" of collecting the surface water apart from the sewage, so that the sludge contains a proportion of road detritus varying with the rainfall. As the weather was fairly dry when my sample was collected the admixture from this source was not excessive. This sludge was received by me in a very wet condition. The cakes contained nearly 60 per cent. of water, and no doubt had not been submitted to pressure for a sufficient length of time on account of the filter-presses at Coventry having to deal with a much larger quantity of sewage daily than they were designed for. The bags in which the sludge was kept were quickly and completely rotted, and the exposed surfaces were covered with a thick white mould. The cakes of sludge became consolidated into one mass, cutting under the spade like clay, and emitting foul gases as the internal cavities were cut into. When weighed up for use in May it still contained 36½ per cent. of water, and had to be put on the land in the form of soft clods too adhesive to be easily broken up by cultivation operations.

**Leyton Sludge.**—The sewage is treated in precisely the same manner as at Coventry, but the nature of the locality is entirely different. Leyton is a rural and suburban district with no manufactures of any kind contributing to sewage, so that the latter may be taken as wholly made up of the refuse and excreta from dwelling-houses and road drainage. For this reason the Leyton sludge would be expected to be more nitrogenous, and to possess a higher agricultural value than either of the other sludges, and doubtless this would be the case could we ensure similar conditions as regards the time and manner of collecting the three samples, and as regards the various accidental circumstances which affect the composition of particular batches of sewage. But of the actual samples which are the subject of the present paper, it is interesting to note that the Coventry and Leyton sludges differ principally in the percentage of water originally present, and in the amount lost by air drying in the bags during the interval from February to May. The Coventry sample was the wettest of the three, and the proportion of water it lost by air drying was least of the three. But the percentage composition of the *dry* Coventry sludge is identical, so far as important constituents are concerned, with that of the *dry* Leyton sludge, and both differ from the *dry* West Ham sludge in containing a much larger pro-

portion of road detritus, so that the West Ham sludge is decidedly richer than the other two in nitrogen and phosphoric acid—the two constituents of direct manurial value.

The cakes of Leyton sludge, as received by me direct from the presses, contained about 50 per cent. of water. This was reduced by air drying in the bags between February and May to 21 per cent. The bags were rotted to some extent, but the sludge remained soft and was almost friable, so that it could be reduced to a fairly fine state of division by ordinary farm implements and operations, and to this circumstance I attribute the fact that although not the richest sludge it gave the best crop of the three experimented with.

*West Ham Sludge.*—This is the result of precipitation by sulphate of alumina and milk of lime of the sewage of a large and thickly populated manufacturing district. The manufactures are of the most varied class, and some of them are of a very polluting character. The sewage is very foul and difficult to treat, but the precipitation is pretty complete. The pressed cakes of sludge had been kept sometime before being sent to me, so that they were partially air-dried, and contained about 30 per cent. water. In consequence of this the bags in which they were kept remained fairly intact in May, and the manure was then in a much drier condition than the other two samples, and contained only 15½ per cent. of water. On the other hand it had become so hard as to resist all attempts to reduce it to anything like a fine powder by means of the pick, shovel, or rake. It resembled, in fact, partially dried clods of a clay soil, and was in the same intractable state to cultivation. Nothing short of a mill would have sufficed to reduce it to a fit state for economical employment. To this cause I attribute the fact that although a much richer sludge than the other two, the crops yielded by the employment of an equal weight of it were not sensibly superior. The sludge also differed from the others in appearance, being grey or slate coloured, like a dark sample of superphosphate. But the principal difference lay in the fact that it contained a much smaller proportion of road detritus, being, I suppose, obtained from sewage collected at a period of less rainfall.

It is this admixture of road dirt which is the chief agent in reducing the manurial value of *dried* sewage sludge.

The "organic matter" of the three samples of sludge experimented with would have contained, in a dried and pure condition, 5.17 of nitrogen in the Leyton sample, 5.20 in the Coventry sample, and 4.51 in the West Ham sample; but whereas the two former samples of dry sludge were diluted with 74 per cent. of mineral matter, consisting chiefly of road dirt, and the percentage of nitrogen was thereby reduced to 1.35 and 1.36 respectively, the *dry* West Ham sludge contained only 60 per cent. of mineral matter, and its percentage of nitrogen was 1.82.

The detailed analyses of the samples of sewage sludge employed are as follow:—

As regards the phosphoric acid contained in sewage sludge, it seems to be chiefly in combination with alumina as precipitated phosphate of alumina. In one sample a mere trace of phosphoric acid was dissolved out by prolonged boiling with acetic acid, and in the other two insignificant fractions. On the other hand, a large proportion of the phosphoric acid in all three samples was soluble in citrate of ammonia of sp.gr. 1.09, the recognized reagent for phosphoric acid precipitated in combination with lime, iron or alumina. One result of the experiments now being described is that they give a very decided manurial value to this precipitated phosphate of alumina; excellent crops of swedes being obtained with the sludge under circumstances where, without assimilable phosphates, no crops worth speaking of could be grown.

Having little more than 5cwt. of each kind of partially dried sludge at my disposal by the beginning of May, I was not able to undertake any very extensive series of trials, or to arrange my plots on a very large scale. I, therefore, marked out 20 plots of  $\frac{1}{10}$  acre each, on No. 7 field of the College farm, then about to be sown with Swedish turnips. No. 7 is a field of 25 acres on the chalk downs; the soil is a thin, poor, calcareous gravel or sand, requiring to be liberally treated in order to yield fair crops. I selected this field because it was in particularly poor condition, having received no farmyard manure since 1880, at all events. In the spring of 1882 it carried vetches, followed by late turnips fed off on the ground by sheep; a crop of oats was taken in 1883, after which the field was ploughed up and lay fallow until May, 1884, when, as mentioned above, it went into swedes. Like all the chalk down fields, after a similar course of treatment, it was then incapable of growing an agricultural crop of swedes or turnips without the employment of superphosphate or of farmyard manure—the yield of the few unmanured plots varying from  $\frac{3}{4}$  tons to  $7\frac{1}{2}$  tons per acre of small and ill-shaped roots.

About the end of May the field was cross ploughed, twice dragged, twice harrowed, and rolled. The whole field, except the experimental plots, was then drilled, by means of a Reeves' water drill, with 3lb. seed and 4cwt. mineral superphosphate per acre. The superphosphate used was of ordinary quality, containing 26½ per cent. of tricalcic phosphate rendered soluble. This quantity of superphosphate, without any farmyard dung or other nitrogenous manure, sufficed to give a good, even crop of swedes over the whole field, the yield averaging 11 to 13 tons of roots per acre. It was at one time in contemplation to top-dress the crop with 1 or 2cwt. nitrate of soda per acre, but the utility of this was considered doubtful, and the results obtained with the two experimental plots which received nitrate of soda in addition to superphosphate, seem to show that no adequate return for the expense of such a top-dressing would have been obtained. It must be borne in mind that swedes and turnips respond especially to the application of phosphatic manures, and that in many cases little or no result is obtained by the addition of nitrogenous manures.

The experimental plots were each  $110 \times 22\frac{1}{2}$  links, the width being exactly twice the width of the drill, so that the ten rows of seed assigned to each plot were deposited during one forward and one backward journey of the drill. The 20 plots formed 20 oblong strips, ranged side by side, and numbered in regular order from the lowest (No. 1) to the highest (No. 20), between which the ground sloped uniformly. In consideration of the rather small size of the plots, and of the irregularity introduced into all manuring experiments by the natural variation in the soil, as many as four out of

the twenty plots were left unmanured. These were Nos. 1, 8, 14, and 20, and the results obtained on these show that the worst patch of land was in the neighbourhood of No. 8, the best land was between No. 14 and No. 20, and the land in the neighbourhood of No. 1 was of intermediate quality. It is very important to bear this in mind in interpreting the results obtained, which would otherwise appear to contain anomalies. One of the unmanured plots (No. 14) yielded more than double the crop obtained on another unmanured plot (No. 8) the difference being occasioned chiefly by the very variable depth of soil in fields of this character, the underlying chalk being nowhere far from the surface, and in some spots being so close as to be turned up by the plough.

Most of the manured plots were in duplicate, the individuals of each pair being placed at a distance of several plots apart. The result of this arrangement is that although two similarly treated plots may not yield even approximately equal weights of roots, yet the mean of each pair is rendered much more reliable than when two similarly treated plots adjoin each other.

The plan of the plots, the kind and quantity of manure used on each, and the weight in pounds of nitrogen and phosphoric acid per acre supplied by each dressing, are set forth in the annexed diagram:

1.	

The dressings of farmyard manure and of sewage sludge were spread on their respective plots and ploughed in, and the ground harrowed and rolled before drilling the seed. The dressings of superphosphate and of coprolite were simply broadcasted by hand before drilling. The nitrate of soda on

plots 6 and 19 was applied as a topdressing on July 18th, after the hoeing, cutting out, and singling of the plants.

The whole field, including the plots, was sown with swedes, on May 30th, 1884, and following days, during a spell of fine dry weather, with easterly winds. Rain, however, fell a few days afterwards, and the plant came up over the field much better than had been expected. The entire season was too dry to be very favourable to root crops or to the action of manures, but a very fair crop was nevertheless obtained all over the field and on such of the experimental plots as had been suitably manured. Patchiness here and there showed the influence of the dry weather experienced during the early days of growth. There was a good deal of mildew on the leaves, and as regards the plots, the plants on the

unmanured plots were observed to be the greatest sufferers. A certain degree of clubbing, also, was observed in the roots on these unmanured plots. Very striking differences between the various plots were visible from the first appearance of the plant, and towards the end of the period of growth the worst plots, viz., the unmanured ones, and the best plot, viz., that which received the heaviest dressing of farmyard manure, could be easily identified from the opposite hillside. The roots on all the plots were pulled the first week in December, counted into heaps on the ground, deprived of their leaves, and weighed. The number of roots on each plot, gross weight of roots, and average weight per root, are given in the annexed table. The mean yield of each set of plots is calculated into tons and cwts. of roots per acre.

MANURE PER ACRE.	No. of Plot.	No. of Roots.	Weight. lb.	Weight per Root. oz.	
None.....	1	429	315	12½	= 6 tons 3¼ cwt. per acre.
	8	325	195½	9½	= 3 .. 9½ .. ..
	11	500	400	12½	= 7 .. 2½ .. ..
	20	326	385½	18½	= 6 .. 17½ .. ..
	Mean.	395	331¼	13½	= 5 .. 18 .. ..
5 tons Farmyard Manure .....	2	466	564	19½	= 10 tons 1½ cwt. per acre.
10 tons Farmyard Manure .....	9	554	760	22	= 13 tons 11½ cwt. per acre.
2 cwt. Ground Coprolite .....	5	161	467	16	= 8 tons 6¼ cwt. per acre.
	15	513	515	15½	= 9 .. 3 .. ..
	Mean.	504	491	15½	= 8 .. 15½ .. ..
2 cwt. Superphosphate .....	4	400	338	14½	= 6 tons 8 cwt. per acre.
	17	461	674	23½	= 12 .. 0½ .. ..
	Mean.	432	516	18½	= 9 .. 4½ .. ..
4 cwt. Coprolite .....	10	459	420	14½	= 7 tons 10 cwt. per acre.
4 cwt. Superphosphate .....	11	508	622½	19½	= 11 tons 2½ cwt. per acre.
2 cwt. Superphosphate .....	6	485	440½	14½	= 7 tons 17½ cwt. per acre.
	19	360	397½	26½	= 10 .. 13½ .. ..
	Mean.	423	519	20½	= 9 .. 5½ .. ..
5 tons West Ham Sludge .....	3	407	473	18½	= 8 tons 9 cwt. per acre.
	13	527	583	17½	= 10 .. 8½ .. ..
	Mean.	467	528½	18	= 9 .. 8½ .. ..
5 tons Coventry Sludge .....	7	470	423	14½	= 7 tons 11 cwt. per acre.
	16	440	622	22½	= 11 .. 2½ .. ..
	Mean.	455	522½	18½	= 9 .. 6½ .. ..
5 tons Leyton Sludge .....	12	534	538	16	= 9 tons 12½ cwt. per acre.
	18	403	605	21	= 10 .. 16 .. ..
	Mean.	469	571½	20	= 10 .. 4 .. ..

Arranging the crops in order of merit according to the mean results given above, we have:—

	Tons. Cwt.		
1.—10 tons Farmyard Manure .. (1 plot) ..	13.	14	roots per acre.
2.—4 cwt. Superphosphate .. (1 plot) ..	11.	21	" "
3.—5 tons Leyton Sludge .. (2 plots) ..	10.	14	" "
4.—5 tons Farmyard Manure .. (1 plot) ..	10.	14	" "
5.—5 tons West Ham Sludge .. (2 plots) ..	9.	84	" "
6.—5 tons Coventry Sludge .. (2 plots) ..	9.	64	" "
7.—2 cwt. Super. 2 cwt. Nitrate (2 plots) ..	9.	51	" "
8.—2 cwt. Superphosphate .. (2 plots) ..	9.	11	" "
9.—2 cwt. Coprolite .. (2 plots) ..	8.	154	" "
10.—4 cwt. Coprolite .. (1 plot) ..	7.	10	" "
11.—Unmanured .. (1 plots) ..	5.	18	" "

The only result in this series of averages that I consider open to much doubt is that which places the manurial effect of 4cwt. ground coprolite below that of 2cwt. The 4cwt. coprolite was tried on one plot only, and this was next but one to the worst unmanured plot of the series (No 8); whereas the 2cwt. of coprolite was tried on *two* plots, each situated near the good unmanured plots. We may therefore disregard this comparison, which is, moreover, a little outside of the present discussion.

The best plot, in spite of its unfavourable situation, was that which received the heavy dressing of 10 tons farmyard manure per acre. Next comes the one receiving 4cwt. superphosphate. The crop on this plot was fairly level with the yield over the rest of the 25 acres of roots all receiving the same dressing. And it is worthy of notice that these two plots represent ordinary farming practice—a good dressing of dung, if it can be spared, if not, 4cwt. superphosphate per acre, or its equivalent in dissolved bones or any similar manure.

We next come to the smaller dressing of five tons farmyard manure per acre, giving a crop slightly less than that of an equal weight of Leyton sludge, slightly greater than that given by equal weights of the other two sludges. The actual results given by equal weights of the three sludges, are in fact, practically the same, although the Coventry and Leyton sludges contained scarcely more than two-thirds of the phosphoric acid, and scarcely more than half of the nitrogen supplied in the West Ham sludge. I attribute this discrepancy entirely to the fact previously mentioned, that the West Ham sludge was much too hard and cloddy to be reduced to a proper state of division by farm implements and operations. It was considered, at the time of putting it on, a most unpromising manure by those who had to do with it, and although, much to their surprise, it produced a very fair crop of uniform, well shaped, and excellent roots, a glance at the actual weight of phosphoric acid and nitrogen contained in the various dressings will show that the manurial constituents contained in it did not exert more than a fraction of their proportionate effect. The same observation is true, to a smaller extent, of the other sludges.

We are faced, indeed, with the fact that 53lb. of phosphoric acid in superphosphate, without the addition of any nitrogenous manure, or 60lb. phosphoric acid in farmyard manure accompanied by 120lb. nitrogen, produced a considerably larger crop than 180 or 240lb. of phosphoric acid *plus* 100 or 170lb. of nitrogen applied in the form of sewage sludge.

As regards the nitrogen, we are, I think, debarred from attempting any comparisons. The application of 4cwt. superphosphate alone, without any nitrogen, produced not only on the plots but over the whole field, an excellent crop of roots, and one only slightly inferior to that obtained by the highly nitrogenous heavy dressing of dung, which was at the same time richer in phosphoric acid. Moreover the 2cwt. of superphosphate without nitrate of soda, has produced almost exactly the same yield as when

supplemented by a top dressing of 2cwt. of nitrate. So general is the experience of farmers in this respect, that the use of nitrate as a top dressing for turnips or swedes is very exceptional, and where guano, dissolved bone or other nitrogenous fertiliser, is used instead of the much cheaper mineral superphosphate, the economy of such a course is very often doubtful. I believe the true statement of the case to be that a moderate crop of roots (*i.e.* turnips and swedes) is in most cases more cheaply grown with 2 to 4cwt. mineral superphosphate per acre than with any other dressing; and when the crop is to be forced beyond this point nitrogenous manure must be used in conjunction with *heavy* doses of phosphoric acid.

Coming back to the fact that the phosphoric acid of the sludges (without reckoning the nitrogen) did not exert more than one-fifth of its theoretical effect, I find the explanation in the unsuitable physical character of the cakes of sludge as they leave the filter-presses, or even after being air dried. The newly-pressed cakes, containing 50 per cent. or more of water, are considerably richer in nitrogen than farmyard manure, and more than double as rich in phosphoric acid; and a large proportion of this phosphoric acid is soluble in citrate of ammonia. Nevertheless, we find that these cakes, even when air-dried down to 20 per cent. of water, are of no greater manurial value, weight for weight, than farmyard dung. The loose texture of farmyard manure, its large percentage of soluble constituents, when well rotted, and its readiness to undergo oxidation, all favour the distribution of its fertilizing elements throughout the soil; the closely compacted particles of pressed sludge, on the other hand, offer the greatest resistance to mechanical and chemical disintegration. As a matter of fact the sludge plots, in my experimental series, were all readily identified when the roots were pulled by the presence of unbroken and undecomposed clods of cake, which had evidently given up at most a small portion of their valuable ingredients to the soil. The utmost a farmer can be expected to do, who buys and carts away the sludge direct from the presses, is to loosely stack the cakes under cover until they have air-dried to a certain point, which it is important not to stop short of, nor to go beyond. With most sludges I should take this point to be reached when the sludge contains rather under 20 per cent. of water. The cakes are then as friable as they are capable of becoming, and like soil when in a fit condition for ploughing, dragging, harrowing, and rolling, they may be cultivated down to a certain fineness of tilth by ordinary farming appliances. But the fineness attainable in this way is far from being sufficient, in the case of sludge cakes, to give them anything like their full manurial value. To effect this, I consider that they should be reduced to as fine a state of division as guano or superphosphate, and from such a product I should expect to get as high a "duty" per unit of nitrogen and of phosphoric acid as can be got from farmyard manure. It is clearly impossible to grind the sludge finely without first drying it, and this drying is also highly desirable, in order to produce a manure of sufficient value to pay for transport by rail to a moderate distance. Dried and ground sludge containing  $1\frac{1}{2}$  or 2 per cent. of nitrogen and 2 or  $2\frac{1}{2}$  per cent. phosphoric acid should be worth something like £1 10s. or £2 per ton, if we value the nitrogen at 12s. per unit, and the precipitated phosphoric acid at 4s. per unit. It must be understood that I merely use these figures for the purpose of illustration, and even a considerable alteration in these will not destroy the form of my argument. The price actually realized by the wet sludge, containing 50 per

cent. of water, is, I am informed, but 2s to 2s. 6d. per ton at Coventry, and at most places the sludge is quite unsealable, and has to be carted away at the public expense, and got rid of in a more or less mysterious manner. It is, for example, taken down the Thames in barges, and pitched into the river at what is considered a safe distance from the Metropolis. I gather from Mr. Hutchinson's paper, already referred to, that the cost of filter-pressing sewage sludge does not exceed 2s. 6d. per ton of pressed cake at Coventry, although the pressing is there carried out under rather disadvantageous conditions. With more than half the water removed from the sludge at this trifling cost, it seems to me not unreasonable to suppose that the cakes of sludge can be dried, ground, and marketed as a manure at a price which should pay all necessary and proper expenses. A good deal of the remaining water can be removed from the pressed cakes by air-drying under suitable conditions, and if the air-dried sludge is ground in its most friable state the cost of grinding should be small.

Although the matter contained in this paper is perhaps rather agricultural than chemical, I have preferred to read it before a society of chemists and engineers, because at present the sewage sludge question concerns them, and not the farmers. Farmers cannot reasonably be expected to buy or bother themselves with such an unpromising material as wet sewage sludge even in its filter-pressed condition, although that is a great advance on anything attainable before the era of filter-presses. On the other hand I see no insuperable obstacle to bringing it into a form in which farmers would be glad to buy it at its full value—and possibly at more.

I have procured through Messrs. S. H. Johnson & Co., another sample of Coventry sludge, dried and ground as suggested in this paper. It is a fine dry powder, not offensive in any way, and contains by analysis only  $13\frac{1}{2}$  per cent. of water. In its dry state it contains 75 per cent. of mineral matter, a figure almost identical with that of the sludge from the same works experimented with last Spring. With this sludge, and another dried and ground sample resulting from Hanson's process of sewage precipitation with lime and alkali waste, I intend to experiment this season on a crop more responsive to nitrogenous manures than swedes or turnips, and I am confident of getting out of the sludge results closely approaching its calculated manurial value. I have added to the list a sample of the Native Guano prepared by the A.B.C. process—a sewage product which, chiefly owing to the attractive form in which it is offered, has for several years sold at least up to its full calculated value.

Notices of papers and communications for the meetings to be sent to the Local Secretary.

Tuesday, November 25th, 1884.

MR. WATSON SMITH IN THE CHAIR.

The CHAIRMAN in the first place briefly called attention to the fund which is being raised on behalf of the widow and family of the late Mr. Henry Watts, F.R.S., and in doing so referred to the good example set by the Birmingham Section. (See notice on the first page of present issue of this Journal, and page 609, vol. III.) Secondly, he directed the notice of members to the full abstract of a Rivers' Pollution Bill, prepared by Mr. Hastings, Earl Percy, and Col. Walrond, appearing in the November number of the Journal for 1884, and hoped they would carefully consider the text of this bill with a view to preparation for an early discussion on the subject, one of the greatest importance for chemical manufacturers. He then called on Mr. Sansone to read his paper:—

## TURKEY RED AND ALIZARIN DYEING ON COTTON.

BY A. SANSONE,

*Dyeing School of the Manchester Technical School.*

I INTEND to give to you first a brief outline of the process of Turkey red dyeing in order that I may afterwards be able to discuss the scientific principles on which rely this important process of manufacture.

Turkey red dyeing has experienced a complete transformation in the last 10 or 12 years, and much progress has been made in this branch of industry, but in spite of this we are as much in the dark now about the theory of the formation of the brilliant red lake on the fibre as we were 20 years ago, in fact the theory has still to be made. It is especially in the important preparatory process of the oiling of the goods where no satisfactory explanation has been given until now.

We have seen a new method of oiling of the goods introduced into practice, and we have seen the old emulsive or Gallipoli oil (the *huile tournaute* of the French) to a great extent driven out of the Turkey red dye works by the modern preparations from castor oil, and we may see perhaps the latter superseding the former completely, and not even then, I am afraid, shall we have had an explanation of the theory of its employment.

Turkey red dyeing, as many other useful arts, has come to us from the East, and judging by its name, it must have been through Turkey that it has penetrated into Europe, and in fact the town of Adrianopolis was at one time famous for the reds it produced, and both in French and Italian the translation for Turkey red is Adrianople red. The processes, as they were originally practised, varied of course greatly from those at present in vogue, and like in all other industries Turkey red dyeing has passed through several stages of progress. At the time of madder dyeing great improvements were made already in shortening the length of the processes, and also in reducing to a minimum the amount of the raw materials employed. At one time as much as 50 per cent. of emulsive oil was used for the oiling of the goods, while the amount of alum was also over 50 per cent., and as far as madder was concerned 150 per cent., and 160 per cent. of the weight of the cotton was believed to be necessary for obtaining full shades. Little by little these amounts came to be considerably reduced and brought down to more reasonable proportions. The time employed was at first also very

long, and was originally counted by weeks, then by days, until in some works it was boasted that a good Turkey red on yarn could be dyed in three days, and I know of an old dyer who could accomplish this feat, although the process in ordinary work would take much longer, but I know for certain that it could be done, and was actually done in some cases. The introduction of garancine at the time also brought about a further improvement, and the clearing processes were also considerably shortened. But artificial alizarin has caused the great revolution in the practice of Turkey red dyeing, and the transformation has been completed by the introduction of the Turkey red or alizarin oils.

But in my mind we are not yet at the end of the transformations in this industry, and no doubt a quicker method of dyeing will be introduced at some future time.

I consider that we are now in a transitory stage between the old method of the Turkey red dyeing and the future processes, which will once be introduced when we shall have more knowledge as to the theory of its formation than we now possess.

The older processes required the cotton to be oiled several times (six or more times), and each treatment with the oil was followed by long exposure in the fields; later on stoves were introduced, and the number of oil passages was little by little reduced until ultimately three passages were found sufficient, while by the modern processes one previous passage in a good castor oil preparation is deemed sufficient to produce a good colour.

Alizarin was introduced into the Turkey red dye works in 1871 and 1872; and in 1873 I visited, in company with a friend, some of the principal Turkey red dye works in Switzerland and found that alizarin had displaced madder completely, and this in spite of the high price at which alizarin was sold at that time. The speedy success of artificial alizarin was due principally to the brighter shades that could be obtained, and the shortening of the processes, which required no more such heavy preparation of the yarns and such severe and expensive brightening operations, although it must be said also that Turkey red yarn dyed with alizarin was received at the time with great mistrust, and that it encountered some opposition at the hands of the weavers, who complained that the cotton was too greasy and could not be easily sized for weaving. There was in fact a certain amount of truth for this complaint since the yarns which were dyed at the beginning were dyed on cotton which had undergone the same oiling operations as for madder, but had not been exposed to the long boiling in soap and soda when brightening as by the old process, and therefore all the useless fat had not been removed, but this difficulty was soon got over and alizarin established itself in the practice of the works, although it was maintained by many dyers that the new reds could not be so fast as those obtained by means of madder. This assertion was also easily disposed of when the new reds had been fairly tried, and the goods produced found to answer just as well as those obtained by means of madder, which could beside never have produced the same bright shades obtained by means of alizarin. Although Turkey red goods are now mostly produced by means of the artificially prepared Turkey red oils or alizarin oils I do not mean to say that olive oil has been completely abandoned, and some establishments still use the latter for the oiling of their goods, and employ, in a certain way, a modified form of the old and classic process of Turkey red dyeing, and some still employ two weeks, and some even four weeks, in the production of their reds, and claim to obtain better results than by the new and shorter process,—in fact

some dyers go so far as to assert that truly fast colours can only be obtained by oiling the goods in the old fashioned way, and that the reds produced by means of modern Turkey red oils, although of very bright shade, do not come up to the others in point of fastness.

I think, however, that if a modern process of Turkey red dyeing be well conducted, as bright and as fast colours can be produced as by the modified old method. The other assertion that colours dyed with alizarin are not so fast as those formerly dyed with madder has been disproved over and over again, and over ten years' experience of the alizarin dyed colours are a convincing proof that such is certainly not the case.

If I dwell on this point it is principally on account of a most astonishing statement which has appeared in some foreign journals, and has been reproduced by the *Manchester Guardian* (of the 4th of this month), viz., that the culture of madder was about to be started again in France, and that the question was seriously being discussed in commercial circles at Avignon.

That the countries and the districts that had once the flourishing madder culture still entertain hopes of their being able to resume its cultivation is a fact that no one need be astonished at, and last year while still in Italy, and in a place near Naples where madder was very extensively cultivated, I was repeatedly asked if there was any probability of madder being employed again in dyeing and printing, since it was stated that some agriculturists intended to resume its cultivation, and there are some of them who year after year have been in the habit of planting small lots of madder root in order to obtain the seed, with the hope that the profitable cultivation of madder would once more be established. Alas, for their hopes, I am afraid madder cultivation is now a thing of the past, and will never be resumed. I am, so to say, directly interested in this subject, since my family was extensively engaged in the madder trade, and the appearance of alizarin caused a great loss to the place where I was born.

I should not have mentioned this matter but for the other assertion found in the article of the *Guardian* above referred to, in which it is stated: "It appears that after several years experience printers and dyers are manifesting a distinct tendency to return to the use of vaucluse (French) madder." It is further stated that prices are rising, and the demand increases daily.

As a matter of fact madder has been for the last few years only employed in pretty large quantities in woollen dyeing, cotton dyeing, and printing, only taking limited quantities, especially in the United States, where on account of the monopoly alizarin has been sold for several years at double the price that it was paid for in this country.

The rise in prices may have been caused by the exhaustion of old madder stocks existing, but certainly not by the increased demand from cotton dyers or printers. And as far as woollen dyeing is concerned after Mr. Hummel's interesting paper, to which we had the pleasure to listen at our last meeting, and the results obtained, there is ground to expect that madder will also be driven off from this branch of industry.

I intend to describe now in a short way the modern process of Turkey red yarn dyeing as it is generally carried on, but I must here observe that the methods vary a great deal according to the different works. I will devote my remarks especially to the dyeing of yarns, although I must say that the same methods, with a slight modification, can also be employed for cotton cloth.

The goods are first boiled or scoured in closed apparatus, generally working under pressure; in some cases iron kiers worked by steam are employed for the purpose, in some others, and this especially on the continent, copper vessels are used heated by steam or free fire; soda ash is principally employed as the scouring agent. After this operation some dyers in this country make it a practice to pass the goods through the bleaching process in order to have the yarn white or half white, while in my own country, or at all events in our case, we never did and never do bleach our yarns before dyeing, as we find the sun does the work for us, since we do all our dryings in the open air, of course when the weather allows, and we can see the cotton whiten under the influence of air and light during the different operations of mordanting the goods.

After the scouring or bleaching, the goods are well washed and dried again, then follows the *oiling*, which is a very delicate operation, and on which depends the success or failure of the subsequent operations.

The prepared oil for Turkey red dyeing is either bought ready made or is prepared in the works; in either case it must be said that if no properly prepared oil is at command no good results will ever be obtained. The Turkey red oil goes under different names in the trade, as for instance: alizarin oil, olein, &c., and is manufactured by several firms here and abroad of excellent quality. It is simply dissolved in water in different proportions according to the depth of shade required, the amount varying from 5 to 12 or 15 per cent. of oil to 100 parts of water, to which sometimes a small quantity of ammonia is added to be sure that there is no free acid in the oil solution. The yarns are passed in this oil solution, then wrung. For these two operations special machines have been devised, which have been found for years very useful in Turkey red yarn dye works, and which perform both the passing of the hanks in the oil preparation and wringing. Sometimes also specially constructed presses are used for the purpose of squeezing out the surplus of the oil mordant, but where no machinery can be employed both operations of mordanting in oil and wringing are performed by hand, care being taken in all cases to do the wringing as evenly as possible in order to obtain even colours.

After wringing the hanks are first dried in the open air, where this is possible, or else brought at once into the stoves where they are left for several hours, and this not only for the purpose of solely drying the goods, but also in order to fix or rather to modify the oily preparation that it will act afterwards as a mordant. The temperature of the stove must not be too high, especially at the beginning, or else uneven colours will be obtained: about 50° C. is deemed by some sufficient, while others go even higher or lower according to their experience. Some dyers prefer to give two passages in oil instead of one. The hanks are taken from the stove and mordanted with acetate of alumina (red liquors.) Here again different opinions prevail, some use acetate solution of 6° or 8° Tw., some use it more concentrated, some use even it weaker, some employ a basic acetate, all depends of course from personal experience. When mentioning of the theory of the formation of the red lake on the fibre it will be seen that not knowing the exact chemical combination that takes place in the process there is no rule to go by, and it is only by experience that we can judge of the different conditions of working, and the amount and strength of raw materials to be used in order to obtain bright reds.

For the operation of mordanting in acetate of alumina the same kind of machines are employed

which are used for the oilings, and of course the wringing must also follow.

The hanks are dried again in the stove, and possibly dyed in the same way as pieces are generally dyed in the printworks, if not they are left to air for a day or two, and this in order to fix as much alumina on the fibre and to drive away the acetic acid.

The dunging is a necessary operation in the modern process of Turkey red dyeing, and this operation is performed in a hot bath principally by means of chalk (whiting) and cow dung, or by means of binarsciute of soda. Afterwards follows a thorough washing, and the goods are ready for *dyeing*. This also is a very delicate operation, and the brightness of the colours also depends from the way it is performed. To prepare the dyebath special brands of alizarins are used, generally known in the trade by the name of alizarin for Turkey red. There are two varieties: one blue shade the other yellow shade, and either one or the other, or a mixture of both is employed, according to the shade which is required, as some markets prefer a yellowish red, while others a bluish brand. I find that the best reds are obtained with products neither too yellow nor too blue. Here also it is only experience that teaches which is the best brand of alizarin to be employed. As a rule all large firms of alizarin manufacturers supply good products for the purpose.

Mr. Levinstein in his interesting address on the alizarin industry, says that it were advisable if makers would offer for sale only the three distinct colouring matters: alizarin, isopurpurin, and flavopurpurin, leaving to the dyers and printers the mixing according to the proportion required, and I am of the same opinion.

The bath is made up with about 7 per cent. to 8 per cent. of alizarin at 20 per cent., and all sorts of ingredients have been recommended to be added to the bath; some dyers have added blood, as it was the general practice when dyeing with madder, some have added glue, some others add a little chalk, acetate of lime, &c., while others find that a small quantity of the alizarin oil and a very small quantity of tannic acid is beneficial, the latter, however, must not be added in large quantity, or else the resulting red, although faster, will lack in brilliancy.

The question of the water is also of great importance, and some chemists go so far as to recommend only distilled water for the dyebath; if the water is not too calcareous it can be employed without any further treatment, while in the case of very hard water it is well to correct the same before use.

The dyeing is started quite cold, and then it is heated very gradually, so that in 1½ to two hours it is brought to about 70–75° C. (Some dyers do not even go so high.) The yarns are, of course, worked all the time, either by hand or by machinery, and the dyebaths are generally made of wood, and heated by steam; and, sometimes, especially in old dyeworks on the Continent, they are made of copper, and are sometimes heated on free fire. Iron vessels I do not like on principle, in fact, for Turkey red dyeing, according to my opinion, iron ought to be avoided as much as possible; and the yarn while working ought never to be allowed to touch any iron; as many lots have been sometimes spoilt by the goods coming in contact with nails, pipes, &c.; and where the iron had touched the cotton, purple spots were formed, which would never disappear. I must say, however, that iron dyebaths for alizarin dyeing, which are so much used in English printworks, do not seem to give any trouble. Very likely after a little use, the iron becomes coated with a thin film, which prevents the further action of the metal. Whichever be the material, or the form of the dyebaths, care must be

taken that the heat be evenly distributed all over the vessel, or else uneven results will follow; in fact, it is advisable to have one or two perforated false bottoms in the beck, in order to compel the steam to pass through the holes, and thus to be distributed all over the dyeing apparatus. A special set of men are generally employed in the works for the dyeing, and, as a rule, they do nothing else but attend to the dyeing, and these men acquire by long practice great dexterity in the art, since it is really an art if the work is done by hand.

In our own place two men can dye in four times, about 400 lbs. of yarn per day; that is, they do four dyeings of 100 lbs. each; and I may add that labour is very cheap over there.

When the bath has reached the desired temperature, the cotton is lifted out of the bath, left to cool, wrung, and dried.

Then follows a second oiling, in which less oil is employed than in the previous one; some dyers add to this oil bath a small quantity of tin crystals and a little ammonia.

The tin chloride which is sometimes also added when the goods are mordanted with acetate of alumina, gives more brightness to the reds, to which it imparts besides a yellowish hue.

The yarn is dried again after the second oiling, and steamed.

Here again the practice varies a good deal in the different works; some steam one hour, some longer, some under pressure, some without, etc. The apparatus employed are sometimes horizontal boilers, hermetically closed, on the same principle as those employed by calico printers; in some other cases they are simply constructed of masonry, as a kind of cistern; in some others, wooden boxes are used. But brighter reds are obtained if the steaming is performed under pressure.

After steaming, the goods must pass the last process of brightening, or rather boiling with soap, in order to remove all the substances which have not been fixed on the fibre, and at the same time in order to brighten the red; this is a necessary operation if fiery reds are required, and it is performed in well-fitted works under a certain amount of pressure by means of a few percentage (about five per cent.) of soap, with the addition of small amounts of soda ash and tin crystals, which are both sometimes also dispensed with. The quality of the soap is of the utmost importance, since if it is at all alkaline it will impoverish the red; therefore a soap must be used which is completely neutral and has been well boiled (thoroughly saponified).

Finally, the goods are washed, dried, and finished, and if intended for export they are made up in bundles of a peculiar form.

As you will easily see, the process as described is anything but a short process, as it is sometimes called, and it is still capable of further shortening and improvements. In some cases it has been tried to do away with the first oiling of the goods, and the cotton has been mordanted at once with acetate of alumina, or other suitable alumina mordant.

Aged, dunged, and dyed with alizarin, then dried, oiled, and steamed, then soaped; and good results are, in fact, obtained by this method, and a large quantity of cotton yarns and cloth are dyed by this shorter process, but I do not consider that by this method as bright and as fast colours can be obtained as by a thorough Turkey red dyeing process, and, in fact, in the trade a distinction is made between Turkey red and alizarin red.

There are, however, some dyers and printers who, by a modification of this shorter method, can produce reds which come very close to Turkey red, in point

of brilliancy, but which are, however, not so fast.

At all events, my personal opinion on the matter, judging from the little experience I have on the subject, is that unless the goods are properly oiled, no proper Turkey reds can be obtained; the colours obtained may be almost as bright, but they will not possess the same fastness as those obtained by the old or rather by the modified classical process of Turkey red dyeing.

The old process is still carried on to a larger extent than is generally believed, and I think the majority of the Scotch dyers still adhere to it.

A good Turkey red will stand bleaching, and, of course, severe soapings, while an ordinary alizarin red will not stand bleaching so well. I want to call now your attention to the patterns and specimens for which I am obliged to two eminent firms who have carried on for years the manufacture of Turkey red goods. I take this opportunity also of thanking the gentlemen belonging to each of those two firms for allowing me to show these patterns to you.

In the production of Turkey red dyed and printed goods this country stands in the front rank for the importance of the quantity produced, and as far as brightness of shade is concerned, the reds produced in Lancashire and Scotland are as fine as those which are produced by the best works on the Continent; but it must be said also that if the Continental production does not come up in quantity, the colours produced abroad are certainly not inferior to those produced in England. I now pass over to the theory of the Turkey red dyeing process.

I must say, to begin with, that there are, and there have been for years, two theories: a chemical theory and a mechanical, or, rather, physical theory.

While some maintain that the fatty substance takes part in the formation of the red lake, by forming chemical combination with alumina and alizarin, others maintain that the oil or fatty matter acts mechanically, by surrounding the alumina alizarin lake in such a way that it forms a kind of coating around the same, and it makes it thus capable of standing the action of soaping and other reagents in a much better way than when it is not protected. The brightness of the Turkey red lake is also explained sometimes by comparison to a varnish, which imparts to a paint greater gloss and brilliancy; for instance, if an ordinary pigment colour is painted on wood, it has no gloss or brilliancy, but if a varnish is applied on the same colour then a quite different appearance will result.

If I have to express an opinion on the matter, I must say that all the explanations are correct if taken altogether, but that they are open to objection if taken separately. In my mind, the fatty substance combines really with alumina, and enters thus in the formation of the lake; and it acts also mechanically, by covering the lake so as to protect the same from the action of soap and other reagents; and it acts besides as a kind of varnish, and imparts thus to the red greater brilliancy.

A discussion is going on among Continental chemists on this very theory of Turkey red dyeing, and I beg to refer those who take interest in the subject to read the articles which have appeared lately in Dingler's *Polytechnisches Journal*. Müller-Jacobs, on one side, considers the prepared oils for Turkey red (which, as well known, are obtained by treatment of olive or castor oil by means of sulphuric acid, washing with water, and neutralising with an alkali) as a solution of the undecomposed oil in the alkaline sulphooleate or sulphocinate, and this solution would act as a mordant, by giving up to the fibre the undecomposed oil in a very finely divided form, and

Then we should have still 2OH group, which would be taken up by lime, i.e.:

Ultimate formula would be: Lime, alizarin, oleic acid lake.

This formula, however, shows one of the many possible formulas, since there are, in fact, no experimental proofs, or, rather, analytical proofs, why two or more molecules of alizarin should not combine with the alumina, instead of one; and it is also not unlikely that the lime itself might combine with the alizarin, by taking up one valence, and thus form a lime alumina alizarate; the possible formulas are rather numerous. In the working of the above equations I simply intended to imply that there are good grounds for a thorough chemical theory, not wishing, however, to state that the formula should be exactly so as I have put them down. In the case of the fatty acid, I have admitted that we had pure oleic acid to work upon, and, in fact, if a prepared oil is used, made by saponification of the acid, it is very likely that the fatty acid enters in the formation of the lake as such, and this, I believe, is actually the case when dyeing an alizarin red; the oily preparation which is used at the end very likely enters in the formation of the lake by the action of the steam to form a kind of alizarin alumina soap lake; I think in this case the fatty acid has not the time to become modified, and enters as such in combination with the alumina. But it is different in the process of Turkey red when the oil is applied at the first on the cotton; in this case it is impossible, in my mind, to conceive that the fatty substance does not undergo any modification when exposed on the fibre to the action of the stoving or exposure to air; in the old process of Turkey red oiling we know for certain that the oil is modified by exposure to air, light, and heat, and that a modified oil mordant is really fixed on the fibre, and does not go away by washing; and, in my mind, when oiling by means of prepared oils, a similar process must take place, and, in fact, a mordant is fixed on the fibre which does not go off when the cotton is washed; but it is not likely that the same modification of the oil takes place in the new as in the old oiling process. It is very likely that in both cases it is a kind of oxydation of the fatty acid which takes place—similar to process of the drying of the linseed oil, but this fact has yet to be proved.

Liechti, Suida and Müller Jacobs speak of the formation of oxyoleic acid and oxystearic acid, and their further investigation will no doubt throw fresh light on this point. It may also be taken for probable that the modified oil does not pass through any molecular change, but simply adds oxygen, but that no change takes place in the acid radicle, and that it is again capable of combining with alumina lime in the same way as before. That there is good proof for admitting that the fatty acid enters really in chemical seems to me to be in the fact that both in the old and new process of Turkey red dyeing a certain amount of heat and pressure is required for the formation of the bright reds, since by the old process the boiling in the dyebecks is necessary for developing the colour, and that pressure is required in the brightening processes to obtain bright shades; in the new process the steaming and also the brightening under pressure produces the same effect. In other words, according to my opinion, it is by this heating that the real combination, in fact a real saponification, takes place.

We could chemically define an alizarin red as a colour in which oleic acid (oromologues fatty acids) forms with alumina, alizarin and lime a combination, a true soap lake.

While in the true Turkey red we also form a soap lake, but the fatty acid is modified in such a way that it acts also physically by covering the lake and protecting the same from exterior influences.

The fact that in the old process of Turkey red such a large amount of the oil is used speaks also in favour of the physical theory, and it is in my opinion due to this excess of modified oil that Turkey red colours owe their fastness against soapings, etc.

It will be remembered that in the old process of Turkey red, especially for dyeing with madder, sumach was generally used; the employment of this can be easily explained by admitting the formation of tannate of alumina, or rather by the tannic acid of the sumach entering in combination with alumina to form a complex formula of alumina tannate, oleate, alizarate of lime.

In my mind there is great analogy between what takes place when the goods are oiled for Turkey red dyeing and the process of drying of linseed oil.

In both cases we have that if we were to employ the oils without any previous preparation that both processes would take much longer to take effect, for instance in the case of linseed oil, if we paint with the raw oil which has not been boiled, it takes several to dry, while the same oil after it has stood a proper treatment, such as is generally termed the boiling by means of a dryer such as litharge, red lead, etc., it acquires the property to dry in much shorter time, in fact in a few hours.

If we take castor oil or olive oil in the natural state they are not suitable for the process of Turkey red dyeing, or rather, if they are suitable for the purpose, they would take too long to accomplish the same object which is accomplished in a much shorter time if the oils undergo a proper preparation; in other words, we have to give to the olive oil or castor oil a treatment which, although different, bears great analogy to the process of boiling of the linseed oil.

I am sorry to say we are also as much, and perhaps even more, in the dark about the proper theory of the boiling of linseed oil, and we are still more ignorant of the chemical changes which take place in the drying, we know that an increase of weight takes place and, although it is stated that it is due to oxydation from the atmosphere, yet it has not been explained how this does happen.

From what I have said concerning the theory of Turkey red dyeing it is evident that much remains to be done until the process can be properly explained, and there is plenty of scope for chemists to devote their time to scientific and practical researches in this interesting branch of industry.

In my mind both the questions, of oiling the goods and the drying of linseed oil ought to be studied at the same time, because there is some analogy between the two processes, although the ultimate results may be different, since olive or castor oil do not belong to the same class of oils to which linseed oil belongs.

I think it is also necessary that experiments should be conducted under the same conditions of exposure, temperature, etc., as they are performed on the large scale; I think also that the different reactions should not be tried by having the mordants in solutions and reacting with the alizarin, in order to precipitate the lakes, since the products thus obtained may not at all correspond to those obtained on the fibres.

It think it is also impossible to examine the change the oil has undergone by extracting Turkey red dyed goods by means of solvents, since if the modified fatty matter is insoluble in the solvent used, only the

unmodified or at all events slightly modified oil would be examined.

I have tried to put myself under the same conditions of working as those which take place in dye works, and yet in such a way that the lake should not be obtained on the cotton but on a material from which it could be easily removed, and I have tried a plan which until now has proved pretty successful, and by following which I hope to throw a little light both on the changes olive or castor undergo when exposed to heat, light and air in a similar way as it is done in practice.

I have employed ordinary window glass plates of different size on which I have applied a solution of prepared oil for Turkey red dyeing and I have exposed the same to the stove and air in the same way as by the manufacturing process, and followed the same through all the stages except the steaming, but I have boiled when dyeing, in order to form the red lake and finally soaped also at the boil.

The red lake clung to the glass in a much better way than could have been expected, and stood even boiling soap if it has not been made to react too long.

As it is I have only performed preliminary experiments, but I hope to obtain by this method some knowledge of the change which the oil undergoes when exposed to air, light and heat, and then to examine the combination which take place at each stage of the process.

It will be seen that that idea is to expose the oil to begin with in a very thin film on a large surface, just in a similar way as it is on cotton where the oil is very finely divided and spread on a very large surface.

The lakes I have obtained are not yet so bright as those which I can produce on cotton, but when I have had a little practice in glass dyeing I hope I shall be able to have as fine reds as it is possible to produce on cotton.

Porcelain plates can be substituted for glass ones, and I think silver sand or glass wool would form also very suitable materials for experimenting upon.

Turkey red dyeing is a very promising field of chemical research, and it will certainly repay any chemist to devote his time not only to try to find out the theory of the process, but also to try to bring further improvements in this branch of industry.

#### DISCUSSION.

The CHAIRMAN: Our thanks are certainly due to Mr. Sansone for his paper, which forms a third contribution on the subject of alizarin and its uses in dyeing, brought before this section. Mr. Levinstein led the way with his valuable essay on alizarin colours and their artificial production. Mr. Hummel followed with the application of the alizarin colours to woollen-dyeing, and Mr. Sansone appropriately succeeds with the present paper on their application in cotton-dyeing. For us in Manchester, of course, the subject of cotton-dyeing is of principal interest. The possible formation of an oleic-alizarine-alumina lake, alluded to by Mr. Sansone, is of interest, and I would draw attention to the fact that the alumina in ordinary *red liquor* mordant exists there, as the so-called triacetate, or more properly, hex-acetate. By the action of heat alone acetic acid is set free from this compound, and the insoluble so-called *di-acetate* is precipitated. It would seem then probable that the oleic acid assists the alizarin to entirely displace acetic acid, so that even the *di-acetate* becomes decomposed, and finally and with increased ease a triple compound is formed with the alumina of a very stable and insoluble kind, as indicated in Mr. Sansone's equation.

#### ON A NEW METHOD FOR EFFECTING DISCHARGES ON FIBRE DYED WITH INDIGO.

BY C. A. FRANC.

THE offer of a medal by the Société Industrielle de Rouen for a new application of vanadium, together with a co-ordinate desire to facilitate the impression of discharges on fibre, dyed with indigo, contributed to the mutual solution of both these problems.

As every indigo dyer knows, the difficulties in effecting pure and regular discharges are not few. By pure discharges, I mean such discharges as will nowise impede the entry of other colours in those places where the colour has been entirely or partly destroyed. In many foreign (chiefly African) markets there is no mean demand for these styles, consisting of combinations of indigo with other colours, chiefly alizarin reds.

The methods for effecting these discharges are very limited. The only one in my recollection is the chromic acid discharge. The principle of its action depends on its power of oxidising indigo to the colourless product isatin. Now the next point for consideration is (1) whether or not this discharge is a pure one. (2) Does there remain on the fibre after this discharge has been effected any substance which would oppose the entry of alizarin colours? To this question my answer is "Yes." When this chromic acid delivers its oxygen to the indigo, converting it into the colourless product, it undergoes an action which, to say the least, finds some portion of it in the fibre as chromium trioxide, a powerful mordant, most objectionable, in fact, I may say fatal, to the entry of pure alizarin reds.

Another objection I beg to oppose to the use of chromic acid is its irregularity and inconsistency.

Another point upon which I beg to base my objection is the tendering effect it exercises upon cotton fibre.

The causes above named have induced me to look for another discharge free from the objections which I have submitted to your attention.

For this purpose I propose metavanadate of ammonia, a substance rendering at the present time considerable service in another branch of the same industry. I first took a mixture consisting of—

50grms. dark British gum dissolved  
in 50c.c. hot water.  
10grms. chlorate soda.  
10grms. acetic acid 67.  
5c.c. tartaric acid.  
75 metavanadate of ammonia.

With this mixture excellent results were obtained.

I now endeavoured to find the minimum quantity of vanadium necessary to effect the discharge. A mixture consisting of—

100grms. British gum.  
10grms. tartaric acid.  
20grms. chlorate soda,

was taken, and before printing, 01grm. metavanadate of ammonia was added, and in spite of the small quantity I obtained good results.

These experiments I made at the Manchester School of Dyeing, under the supervision of Mr. Sansone, to whom I am in no small degree indebted for advice. I will now make a few observations as to the *modus operandi*.

It is a common practice amongst indigo dyers, after the final dip and exposure to air, to give the goods what is technically known as a *souring*. The vat I worked with was a "glucose or fermentation" vat. It was found that if the goods were not extremely well washed after the souring the fibre became rotten after ageing and steaming. I moreover found that if the goods were in any wise

damp, before the discharge was printed they were considerably tendered. This tendering took place, curiously to state, not on the portions of the fibre where the colour was discharged, but on the blue portions where the discharge had never acted.

The same amount of vanadium I found to be effective for light and dark blues, but I found it advantageous in the case of very dark navy blues to add to the colour previously about 1 grm. of oxalic acid for every 100 grms. of gum.

This quantity must not be exceeded, as a larger one has the effect of rotting the fibre. The goods are aged and steamed just as in the case of aniline black. I obtained better results by soaping the whites.

#### DISCUSSION.

Mr. SANSONE: As well known, chlorate of alumina, when applied on the fibre, if exposed to heat or steam, easily decomposes, forming free chloric acid, a powerful oxidiser. This chlorate of alumina has already been utilised by H. Schmid for forming oxycellulose on calico, and prints made by this means have the power of attracting aniline colours only on the spots where the chlorate of alumina has been applied, as the oxycellulose formed acts like a mordant. I thought of utilising this power of oxidation of the chlorate of alumina to produce white discharges on indigo dyed goods, but the whites obtained are not very clear. However, at the same time that the indigo is discharged, alumina is fixed on the fibre, and if the fabric is dyed with alizarin a red is at once obtained. The advantage of fixing alumina mordant on the fibre while the indigo is being at the same time discharged will be easily appreciated by those acquainted with the production of indigo printed and dyed goods. The only drawback found in the working of this process of discharging by means of chlorate of alumina is that the fabric is made rotten if exposed to the action of the steaming, but I believe that by ageing in the same way as for aniline black this tendering of the material could be avoided.

### UNGUENTUM HYDRARGYRI, PILULA HYDRARGYRI, AND HYDRARGYRUM CUM CRETA: THEIR PREPARATION ON THE LARGE SCALE.

BY AD. SOMMER, PH.D.

THE following is an abstract of the author's paper, which latter, at the request of the Chairman, was read before the meeting by Mr. Elborne.

*Unguentum Hydrargyri.*—In the preparation of this substance the author first draws attention to the fact that mercury is capable of more rapid extinction, or being brought to a finer state of subdivision, by prolonged agitation with such liquids as turpentine, olive oil, or resinous tinctures (e.g., Tr. Tolu and Tr. Benzoin) than by the present mode of trituration with fat. For the preparation on the large scale of a commercial mercurial ointment, the author advocates the use of the following formula and method of manipulation:

Mercury .....	50lb.
Olive oil .....	4lb.
Resin .....	4lb.
Fresh beef tallow .....	12½lb.

Upon a solid board, which accurately fits into the frame of a sifting machine having a horizontal motion, are fastened by means of wires and wooden cross-pieces, two ordinary iron mercury flasks. Into each flask are poured 25lb. of mercury and 2lb. of olive oil.

The plugs are then tightly screwed into the openings of the flasks, and the whole apparatus is laid in the aforesaid frame. The latter, which is attached to an eccentric crank, is then set in motion by connecting the latter by means of a belt and pulleys with the shafting of a steam motor, and allowed to be shaken for about eight hours. At the end of this time the mercury is in so fine a state of division that a magnifying glass with a power of ten diameters will show no globules of mercury. In the meantime, the beef suet is melted, and, after liquefaction, allowed to cool to about 50° C. The contents of the two flasks are then emptied into a capacious pan, and about one-fifth of the mixture of liquefied fat and resin added. This mixture is then vigorously stirred till it has become semi-solid, when another portion of the liquid fat, which, of course, by very little warmth, must be kept as near as possible to 50° C., is added to it. These additions and subsequent incorporations of liquid fat are continued until all of it has been added, observing the precaution never to make any new additions before the previous one with the mercurial mixture has cooled down to a semi-solid state. To ensure complete homogeneity the ointment while still warm is passed through an ordinary iron paint mill.

*Pilula Hydrargyri.*—For the preparation of this compound the author adopts a similar method for the extinction of the mercury, and gives the following formula:

Mercury .....	25lb.	} Mixture for one mercury flask.
Glycerine .....	2½lb.	
Water .....	9fl. oz.	
Alcohol .....	9fl. oz.	
Powdered licorice-root .....	3oz.	

These ingredients are all placed in an iron mercury flask, which is shaken precisely in the same manner and by the machine described above under mercurial ointment. After eight hours of shaking, the mercury is found to be finely divided. The contents of the flask are then poured into a large dish, and honey, with energetic agitation added. When the mixture has become perfectly homogeneous, proper proportions of powdered rose leaves, marshmallow, and licorice-root, that are requisite for 75lb. of blue pill mass, are incorporated. The mass is further kneaded by means of a long wooden lever firmly attached to a wooden bench or table.

*Hydrargyrum cum Creta.*—Under this head the author describes in detail a well-known process, which consists of introducing the necessary ingredients, together with iron balls, into a large barrel, and rotating the latter on its axis by the aid of a steam motor for 10 hours, at the end of which time the mercury was found to be thoroughly incorporated.

After reading the paper, Mr. Elborne said that while no doubt the theory of the process for the extinction of the mercury introduced by the author was very good, he did not consider that British wholesale manufacturers of British Pharmacopœia mercurial ointment would be justified in adopting the author's formula, since the latter contained such extraneous substances as resin and olive oil; but for a "commercial" mercurial ointment, that is, one supposed to be of the same strength, but not prepared exactly according to the British Pharmacopœia process, the author's is probably a very good working formula. Mr. Elborne believed that all the unguentum hydrargyri, as at present prepared by the wholesale houses in this country, was made by trituration with heavy machinery; if, therefore, the author's process of extinction by agitation could be adapted to the British Pharmacopœia formula with any great saving of time and labour, he saw no reason why it should not be adopted. The mode of operating with the

British Pharmacopœia formula would then evidently consist in agitating the mercury with the lard, kept in the molten state by the application of heat; whether it would thus yield a satisfactory result he was not prepared to say. As regards the author's process for the extinction of mercury in the preparation of blue pill, it was certainly a novel one, the present mode of extinction adopted in the trade, he believed, being effected by means of a sort of drug mill in which the mercury was ground with honey. In reference to the mode of preparation suggested for the preparation of hydrargyrum cum creta, he believed it was a process already long adopted in this country, and one in which there was probably room for improvement.

MEETINGS, SESSION 1885, Jan. 8th, Feb. 5th,  
March 5th.

General Meeting held in the Lecture Theatre of the  
College of Science December 4, 1884.

MR. J. C. STEVENSON, M.P., IN THE CHAIR.

## NOTES ON THE CHEMICAL AND METALLURGICAL INDUSTRIES OF THE UNITED STATES.

BY WILLIAM MARTYN, BOSTON, U.S.A.

SPEAKING first of chemical industries, and in general terms, we may say that there are five principal manufacturing districts. (1) Boston and Eastern district, (2) New York district, (3) Philadelphia, (4) Baltimore, and (5) Charleston, S.C. There are besides works at Buffalo, N.Y., Cleveland, O., Chicago, Ill., Memphis,

Tenn., St. Louis, Miss., Wilmington, S.C., at three or four places on the Pacific coast, and a good many isolated works elsewhere.

In the Boston, New York, and Philadelphia districts a miscellaneous chemical business is done, including sulphuric, nitric, muriatic, and mixed acids, chemical fertilizers, dyers' chemicals, etc. In the Baltimore and Charleston districts chemical fertilizers are the sole products.

### Sulphuric Acids.

There are about one hundred sulphuric works in the States. They are located all up and down the eastern coast, and at numerous places inland. They are of all capacities from the small works burning one ton of brimstone daily, to the large plant having an annual capacity of upwards of 20,000 tons pyrites. The production of acid during the current year will reach 395,000 tons oil of vitriol. The consumption of pyrites during the year will not fall far short of 75,000 tons; next year it will amount to at least 90,000 tons.

### Brimstone

is usually burnt in the old fashioned burner with cast iron plate. The plate is commonly four feet by eight feet, but sometimes it is wider and often it is longer and narrower. Very often burners are found in the construction of which not a single firebrick has been used. The quality of the red bricks being such that substantial furnaces can be built without the use of the more expensive firebrick. Not unfrequently burners are seen built with solid brick beds. One would naturally expect that such a burner would get so hot in summer that sublimation would take place to an alarming extent, but by reducing the charge—which any way must be done for other reasons—this does not happen. Several Blair furnaces were put up some years ago, but all I think have been abandoned, the proper regulation of the admission of air being not quite so simple as was hoped.

### Grate Burners.

Pyrites is burnt principally in the regular grate burners so well known on this side of the Atlantic. They are mostly a trifle larger than the average burner here, having from 22 to 25 square feet of area at the charging door. I expect shortly to build a block of burners in which I propose to adopt simple arrangements for mechanically shaking the grates and removing the cinders. With such burners I expect to reduce the labour cost for burning to one half the present cost. This where wages are so high as in America will be a not insignificant economy.

### Shelf Burners

for small ore are worked with considerable success, and as American mines produce large quantities of rich and good "small" ore, the use of these burners is likely to extend. Small can be bought at from 3/- to 4/- per ton less than lump ore. Spence's mechanical furnace for smalls have been introduced in one or two works.

A furnace patented by Carter and Walker has been tried for burning smalls, but the success thus far attained has not been very encouraging.

There are three kinds of pyrites used in the States: Spanish, Canadian, and domestic. Speaking roundly 25,000 tons of each will be used this year. The Spanish ore is principally Rio Tinto, only a little Mason's and Tharsis being imported.

### Canadian Ore.

The Canadian ore comes from Sherbrooke, just a few miles from the United States' boundary. There

are two mines: the Crown belonging to the Orford Copper and Sulphur Company, and the Albert, the property of G. H. Nichols and Co., of New York. The ore is sent over about 300 miles of railway to New London, Connecticut, where it is put on board vessels for New York. Canadian ore contains about 40 per cent. of sulphur,  $\frac{3}{4}$  per cent. copper, 3 ounces of silver per ton, and 20 per cent. Silica.

#### Domestic Ores

are all very suitable for acid making, being rich in sulphur, containing only traces of arsenic or even none, and burning freely without clinkering, but they are mostly rather poor in copper, so that the cinder has thus far been of little value. They can be cheaply mined and transported into manufacturing centres. The principal mines are Milan at Milan, New Hampshire, 140 miles from Portland, Maine; the Davis, at Rowe, Massachusetts, 120 miles from Boston; and the Arminius mines at Victoria, Virginia, 40 miles from Richmond. There is a strong probability of the introduction of pyrites from Newfoundland in the coming spring. In fact some has already been imported.

#### Duty on Imported Pyrites.

There is a *duty on imported pyrites* containing not more than  $\frac{3}{4}$  per cent. copper of 75 cents. per ton plus  $\frac{1}{2}$  cents. per pound on the copper when the amount of the latter is over 2 per cent. During the present year only about 25 per cent. of the acid made has been produced from pyrites, but the proportion is rapidly increasing. 45 per cent. of the acid made is used for oil refining, 45 per cent. for the manufacture of fertilizers, and the remaining 10 is for miscellaneous purposes.

#### Glover Towers.

There are now a large number of *Glover Towers* at work, although many good acid makers still question the advisability of employing them. This is partly the result of the indifferent success attending the use of some of the faultily constructed towers first erected, and partly to the fact that the concentrating action of the tower is of no great benefit. At least 45 per cent. of the acid made is used at chamber acid strength, and as Glover tower acid is generally unsuitable for concentrating to 66° Baumé, the acid for this purpose is usually brought to 60° Baumé in lead pans mounted on top of the burners, or placed behind the platinum stills. One or two cases of Glover tower failing to act satisfactorily have been due to their having been placed too far away from the burners and in exposed situations. Several circular towers have been erected, but they are not preferred, as they are difficult to repair. The towers are usually packed with quartz rock from South Paris Maine.

While speaking of Glover tower I may mention that the plan of injecting the nitrous acid into the front chamber by a jet of steam has been quite extensively practiced, and in some cases with great success. At other works this mode of denitration has not given unmixed satisfaction. With a large absorbing space (so as to get the recovered nitre in a small quantity of rich nitrous acids) and watchful care, this plan admits of very good results so far as denitration is concerned, but the cooling action of the Glover tower is wanting (this with brimstone does not matter much) and the 60° Baumé acid for the absorbing tower has still to be concentrated in lead pans. Some very low Glover towers have recently been erected.

#### Chambers.

Coming now to the *chambers*, we find that there as here the extremes of very large and very small chambers have been tried. There is a greater incentive to building chambers with a large cross sectional area than there is here—lead and labour being so expensive, and the desire to keep capital account down much stronger. Chambers 25 to 30 feet wide and 25 feet high are not uncommon. I know of but one instance in which a width of 30 feet is exceeded, and in that case the width is 40 feet. The mode of carrying the top lead of this wide chamber is similar to that adopted at Widnes and perhaps elsewhere. Trussed girders are thrown across the chambers at a distance of about 20 feet apart, and bolted to these are iron loops into which slip the joists—running longitudinally, to which the straps are nailed.

The chambers are usually carried 10 or 12 feet above the ground on wooden posts 8 or 10 inches square, placed on brick pillars 10 or 12 feet apart. The chamber frame is usually built quite strongly the uprights being generally 4 inches by 8 inches placed 4 feet apart, and the rails (or girts) 3 inches by 5 inches, and a like distance apart vertically. Yellow (or pitch) pine is the timber generally used for chamber frames, though not unfrequently the less-reliable spruce and hemlock are seen. The chamber *lead* is seldom stronger than 5lb. per square foot, though of late years the tendency is towards using 6lb. lead. I have even seen chambers built of 4lb. lead, and have known them to work for six or seven years (with brimstone), with little or no repairs, and 5lb. chambers may be seen that have been in constant use for 15 years without any overhauling. The hot summers and cold winters necessitate the complete roofing-in of the chambers. The roof is supported entirely independent of the chamber frame on posts standing in the passages.

At one works I am acquainted with a somewhat peculiar style of working chambers is in vogue. There are three sets of chambers, having in the aggregate a capacity of about 300,000 cubic feet. The residual gas from No. 1 set passes into No. 2, and the gas from the latter goes into No. 3. From the last chamber of No. 3 set the gas is taken to an absorbing tower. This seems like a partial carrying-out of a proposal once made by a works' manager, who mentioned it to me in confidence and asked my opinion of it. He proposed to take the residual gas from the last chamber of the set back to the first chamber, and in this way use his nitre over and over again without the trouble and expense of condensing and vapourising it again. I ought here to say that the results obtained at the above works are fully as good as those at neighbouring works.

As many works the pressure of the *steam* for the chambers is kept perfectly constant by means of an automatic regulator. The pressure at the boilers may vary ever so much, but the steam to the chambers remains perfectly steady. This obviates the necessity of setting apart of a boiler (or boilers) for the chambers alone and conduces very much to a regular chamber process. Whoever has run chambers with a good steam regulator will never do without one again.

#### Concentrating.

For *concentrating* to 66° B., the use of glass is almost entirely abandoned. Faure and Kessler's platinum dish and lead hood are in great favour, especially where pure water for cooling the hood is cheaply obtainable, or where pyrites acid is to be concentrated. The facility with which the dish can be cleaned out is a strong point in its favour where deposition of

solid particles from the acid take place. A considerable number of Johnson, Matthey and Company's new platinum stills are in use, and everywhere give satisfaction.

Quite recently an important innovation in concentrating apparatus has been introduced by Mr. Marinus Willott, of Newport, Rhode Island. It is designed principally with a view of employing in its construction *rolled* instead of the more expensive *hammered* platinum. The apparatus consists of a number of small boilers 3 feet long and 6 inches diameter placed above and behind one another over a fire-grate. The boilers are of rolled platinum  $\frac{1}{16}$ ths of an inch thick, and are connected with each other at alternate ends by means of elbow pipes and loose sleeve joints. One boiler is allowed for each 2 tons of strong acid daily. The cost of the apparatus is said to be only about one-half that of a Faure and Kessler still, of similar capacity. It is claimed that the loss of platinum is not so great as with any existing apparatus, and that the consumption of fuel is less, but it is difficult to see what there is to base such claims upon. The apparatus has been in use almost twelve months, at works with which the inventor is not in any way connected, and has given satisfaction. The weak point about the arrangement seems to me to be the soldered joints all round each end of the boilers.

During the past two years a good deal of 66° B. acid has been concentrated in iron vessels at a works in New Jersey.

The prices of material (in quantity) in New York, Boston and Philadelphia, are about as follows:—

	£	s.	d.	
Yellow (pitch) pine .....	0	1	0	per cubic foot.
Spruce .....	0	0	$\frac{7}{8}$	" " "
Red-bricks (21 per cbr. ft.) .....	1	9	0	" " "
Fire-bricks .....	6	0	0	" " "
Sheet Lead .....	21	0	0	per ton.
Pyrites .....	1	5	0	(2210 lbs.)
Nitre .....	0	10	6	per cwt.
Coal .....	0	16	0	per ton.

Wages run about as follows:—

Carpenters .. .. .	7/- to 10/-	per day of 10 hours.
Bricklayers .. .. .	5/-	" "
Lead Burners .. .. .	16/- to 22/-	" "
Labourers .. .. .	5/- to 7/-	" "
Burnermen .. .. .	7/- to 8 6/-	per shift.

#### *Nitric and Muriatic Acids.*

These are made principally in the New York and Boston districts. The cast iron cylinders used for the distillation, are usually about 4 feet in diameter and 9 feet long. The metal is  $1\frac{1}{2}$  to 2 inches thick. The fire-grate is 3ft. 3in. long and 15 inches wide; it is 3ft. 6in. below the bottom of the cylinder. The charge is usually 800 lbs. nitre, or 1,100 lbs. salt. The cylinders are either worked intermittently—in which case the cylinders are working one day and cooling down the next, and the cylinder cake is removed in the solid state—or else continuously, and the acid sulphate is run off soft. About five per cent. more acid is generally used when the latter mode of working is adopted, but it is mostly preferred to sacrifice that amount of acid and work the retorts to their full capacity excepting where the escape of acid fumes from the liquid sulphate would lead to trouble with the neighbours.

The receivers are of earthenware and are mostly made in Philadelphia; they are from 30 to 35 gallons capacity. The carboys in which the acid is shipped are packed in square wooden boxes.

#### *Mixed Acid.*

A good deal of this is made in the vicinity of Boston, New York and Philadelphia, for the nitrification of glycerine in the manufacture of dynamite and

blasting powders. It consists of a mixture of two parts strongest nitric acid, and one part of 66° B. sulphuric acid. It is sent to the dynamite works in the sheet iron drums in which glycerine is imported

#### *Tin Crystals.*

This is an important manufacture carried on in the neighbourhood of New York and Boston. The crystals are used in the dyeing establishments in the vicinity. Feathered tin is dissolved in muriatic acid in copper pans heated by a coal fire and the chloride of tin solution is crystallised in earthenware dishes two feet in diameter. A quantity of single and double muriates and of oxychloride of tin are also made.

#### *Stannate and Silicate of Soda and Iron Salts.*

These are made near New York, Boston and Philadelphia. A good deal of the two soda salts is imported.

#### *Glaucous Salts.*

These are made, though not in a very large quantity, in the vicinity of Boston and elsewhere. Nitre- and cylinder-cakes are roasted to expel the excess of sulphuric acid, the neutral sulphate passed through a pair of Cornish rolls and dissolved in hot water, the iron is then precipitated with milk of lime, and the liquor, after settling, is run into lead-lined wooden coolers to crystallise.

#### *Bicarbonate of Soda.*

Almost the whole of the bicarbonate used in the country is prepared at home—judging from the extent to which baking powders are used the amount must be not inconsiderable.

#### *Soda Crystals.*

The American name for these is sal soda. Formerly all the crystals used were imported from this country, but of late years a considerable quantity has been made at home from imported soda ash. I think there are good reasons for believing that this branch of manufacture is likely to extend. The duty of 23 shillings per ton and the ocean freight on 12 cwt. of water per ton crystals, form a very good protection, but the very hot weather of an American summer is a great drawback.

#### *Soda Ash.*

Up till quite recently this has not been made in any quantity. For a number of years the Pennsylvania Salt Manufacturing Company have made a little of both ash and caustic from cryolite, at their works in Natrona, Pennsylvania, and within the last twelve months a small quantity of Le Blanc soda for local use has been made from cylinder cake at a large print works on the Hudson river, New York. But the establishment of the Le Blanc process in its entirety in any part of the States seems highly improbable, notwithstanding the protection afforded by ocean freight and a duty of 23s. per ton on ash, and £2 6s. per ton on caustic. Coal and labour are both too dear. Two ammonia-soda works are now in operation at Geddes and Syracuse, in New York State—two salt-producing centres. There are plentiful supplies of strong brine in both New York and Michigan, the two States together producing about 600,000 tons of salt yearly. Little rock salt is mined at present. Ordinary white salt is worth about 21s. per ton in New York.

### Commercial Fertilisers.

This is the name given to chemical manures. They are made at all the chemical centres on the Atlantic seaboard, at Buffalo, New Jersey; Cleveland, Ohio; Chicago, Illinois; in Tennessee, and at isolated works in nearly every State in the Union. The quantity annually made is about 900,000 tons, and is constantly on the increase. Two-thirds of this is made in the Boston, Charleston, New York, and Baltimore districts; Baltimore being at the head of any single district.

The principal phosphoric material is the phosphate rock of South Carolina, 60 per cent. of the phosphoric acid in manufactured goods being derived from this material. Of the remaining 40 per cent., Navassa phosphate rock and bones are the chief sources. The supply of potash is imported from Germany.

For ammoniates, nitrate of soda and all kinds of animal refuse, including a large quantity of fish, are used. Within the last two or three years quite a large quantity of cotton seed has been used as an ammoniate, both by manufacturers and by the cotton growers themselves in the Southern States. Many of the latter have taken to burying plain superphosphate and potash salts, and mixing with them their own crushed cotton seed, the oil of which has been extracted at one of the numerous works erected for the purpose. In this way quite a revolution is going on in the fertiliser trade of the south.

The South Carolina rock is generally delivered at the works in pieces the size of hens' eggs. It is first fed into a grinder, consisting of a semi-cylindrical cage in which revolves a strong shaft carrying worm-like steel blades. In this grinder the rock is reduced to the size of Barcelona nuts, in which state it goes to the burrs. These are usually under runners, and a pair three feet six inches diameter reduces 14 to 20 hundredweight of land rock per hour to 50 mesh. Not much more than half that quantity of river rock can be put through, and the hard kernels play havoc with the burrs.

*Canadian apatite* is not in great favour with American manufacturers. They find it costly to grind, and difficult to get the acid to act on all the particles, and the strong evolution of hydrofluoric acid is decidedly objectionable.

The *acidulation* of the ground rock is effected in horizontal dishes, which revolve round a vertical axis. The pan of the mixer is eight to nine feet in diameter, and 15 inches deep. The stirring is effected by means of a fixed blade. About 2,500 to 3,000 lbs. of rock are put into the mixer at each operation, and six to 10 mixings are made per hour.

The acid is generally used of a strength of about 47° Beaume, the extremes of strength being 46 and 53. After acidulation, the ammoniates (excepting nitrate of soda) are added in the mixer. A central plug, about nine inches diameter, is then raised, the discharging scraper lowered, and the contents of the pan emptied into the bins below.

Several improvements have lately been introduced, one is the *Sturtevant mill*, to do the work of grinders and burrstones, and another is the *Blake system* of fine crushing. Neither have yet been in use long enough to establish the claims made for them. A third innovation is the combining of the milling and mixing into one operation. Friends of mine who have adopted this style of working are pleased with it.

Some manufacture what they call *special fertilisers*; that is fertilisers specially adapted for different crops. Thus they have one fertiliser for potatoes, another for wheat, another for Indian corn, and so on. But

the great majority of manufacturers make only standard fertilisers, containing about

10	per cent.	available phosphoric acid,
24	..	ammonia,
25	..	potash.

In many States the law compels makers of fertilisers to mark on the outside of the package the percentage of the fertilising constituents.

### Bichromate of Potash

is prepared on an extensive scale at a works in Baltimore, Maryland.

### Acetic Acid.

This is prepared near New York, in Philadelphia, and elsewhere, from the distillation of wood.

### Blue and Green Vitriols.

These are both prepared on an extensive scale at different places.

### METALLURGICAL INDUSTRIES.

The United States now stand in the front rank of base as of precious metal producers. In the production of iron she has long taken a leading place. The present annual production of pig is about five million tons; Pennsylvania is credited with 50 per cent. of this, and New York, Illinois, and Ohio with about 10 per cent. respectively. Of *Bessemer steel* the annual output is about 1½ million tons. Most American pigs contain appreciable quantities of phosphorus, so that large quantities of Bessemer pig have still to be imported. The presence of phosphorus in the iron enables foundries to turn out very fine castings. Even furnace castings and such rough work as that will compare very favourably with the best work we are accustomed to see in chemical works at least, on this side the Atlantic.

Coming now to

### Copper,

we find that whereas ten years ago the output of copper outside of Lake—of which some 15,000 tons were produced annually—was quite insignificant. Now the production of copper from sulphides, oxides, and carbonates is some 20,000 tons, and the total output of copper is 50,000 tons per annum. The exports of copper—in the form of argentiferous ores and mattes—during the current year will be more than 10,000 tons.

The leading copper district is still that of *Lake Superior*. The metal, as is well known, occurs in the native state, and is of exceptional purity. It has been mined for about 40 years. At first principally the mass copper—large masses of pure copper—were worked, but the cost of cutting up and handling this was so great that investments in Lake mining were at first not very profitable. Now the copper is principally produced from ore carrying two to nine per cent. of the native metal. The ore from the Calumet and Hecla mines—from which are extracted 60 per cent. of the annual output of Lake copper, and 35 per cent. of that of the whole country—averages 4½ per cent. The ore is crushed and concentrated mechanically to about 70 per cent. copper, and these concentrates are then shipped to the smelting works at Hancock and Detroit. After refining, the ingot copper is shipped along Lake Erie to Buffalo, N.Y., whence it is sent by rail to New York and eastern markets.

The next most important copper district is *Arizona Territory*, from which comes 20 per cent. of the annual output of the States. The ores are oxides

and carbonates, carrying (very frequently) about 15 per cent. of copper. They are usually concentrated by mechanical means to say 25 per cent. copper, and are then smelted—with siliceous fluxes—in blast furnaces for the production of coarse copper, containing say 98 per cent. metal. This is shipped to New York and Baltimore to be refined. Coke for smelting is brought from Cardiff, *via* San Francisco, or from Trinidad, Colorado. It costs at the mine £4 to £12 per ton.

Next in importance comes *Montana Territory*, from which comes 10 per cent. of the total production. The mines and smelting works are all in the neighbourhood of Butte City. The ores are all sulphides, and are invariably argentiferous. The produce varies from eight to 50 per cent., the average being about 10 per cent., and the silver is usually about one ounce per unit of copper. The ores are nearly all largely contaminated with arsenic. The poorer ores are smelted to a 70 per cent. matte, which together with the richer ores, is shipped East to be refined, much of it ultimately finding its way to England.

*New Mexico and Wyoming Territories* are quickly coming to the front as copper producers, and there are likely to be rapid developments there within the next two or three years.

There are five copper smelting and refining establishments on the Atlantic seaboard. The works are located as follows:—

Ansonia, Connecticut.	Ansonia Copper Company.
Taunton, Mass.	Crocker Brothers.
Bergenport, New Jersey.	Orford Copper and Sulphur Co.
Elizabeth, New Jersey.	New Jersey Extraction Works, Limited.
Baltimore, Md.	Pope, Cole, and Co.

There are two wet extraction plants for treating pyrites cinders—one at Elizabeth, New Jersey, and one at Natrona, Pennsylvania.

In regard to the furnaces used for copper smelting in America, we may say that reverberatory and cupola furnaces are both extensively used, often side by side. For the rich oxides and carbonates in Arizona cupola furnaces are exclusively used. For the sulphide ores of Montana reverberatory furnaces are generally preferred for silicious ores, and cupolas for basic ones. The reverberatory furnaces are (sometimes at least) in this case fired with wood. For smelting the Lake Superior ores reverberatories are used, and cupolas for cleaning the poor slags. The works on the Atlantic coast use both types of furnace.

Great attention has been paid to the construction and working of *cupola furnaces*. Those now generally used are water-jacketed furnaces, the construction of which several engineering firms make a specialty of. They are made of circular and of rectangular horizontal section, the larger ones being of the latter shape. They have a capacity of from 20 to 60 tons daily or even more. Where fuel, fire-bricks, etc. are very expensive, as in some of the mining districts of the Far West, this type of furnace is more economical than any other.

At the Orford Copper and Sulphur Company's works Bergenport, New Jersey, there are very large cupola furnaces (not water-jacketed) having a daily capacity of almost 200 tons. At these works the plan of working with *outside wells* has been very successfully introduced. The melted mixture of metal and slag runs out of the furnace as quickly as melted into a moveable well placed in front of the furnace. This well is about 6 feet long, 18 inches wide and 18 inches deep inside. It is formed of an outer shell of boiler plate with fire-brick lining. Across the middle a fire-brick partition is formed which reaches to within two or three inches of the bottom and divides the well into two compartments, each about 2' 3" long, 14" wide and 14" deep. The molten mixture runs into

one compartment near the central partition. The slag flows off at the other end of the compartment in a continuous stream while the matte settles down, and passing under the brick partition into the next compartment is run off into suitable moulds. The works of this company are quite extensive, having a capacity of 300 tons refined copper weekly. They employ very large reverberatories for roasting their white metal and for refining. Quite recently they have erected plant for extracting the silver from argentiferous copper mattes on a large scale.

In *buying copper ores* and furnace products the copper percentage is always determined by electrolytic precipitation from a slightly acid solution. From this 1·3 per cent. is deducted for smelters' allowance. The price is generally fixed at so many cents per pound of copper (say the current or prospective value of fine copper) less so many cents per pound for smelting and refining. This last figure varies of course with the produce of the ore or matte, and likewise with the nature of the ore. The ingots are usually made very much smaller than there are.

### Lead.

The production of lead in the United States now almost equals that of England (including foreign lead smelted here), being nearly 140,000 tons per year. The imports have dwindled into comparative insignificance. The leading lead state is *Colorado*, turning out, as she does, one half the total annual production of the States. More than two thirds of the Colorado lead is smelted in Leadville. There are also very extensive works at Denver and at Pueblo. The ores contain 10 to 20 per cent. lead and about 20 ounces silver per ton. Water-jacketed cupola furnaces are used for smelting, Trinidad (Colorado) coke being used for fuel. The coke costs about £2 10s. per ton delivered. Iron ore, limestone, etc. are used as fluxes. For roasting reverberatory furnaces, 40 feet long, are used, fired with wood or coal.

For working cupola furnaces at high altitudes—as at Leadville—more fuel is required than at places nearer the sea level. This difference is said to amount to as much as 25 per cent. The loss of lead in smelting is about 10 per cent., but is frequently more.

The next most important lead district is the territory of *Utah*. She produces one fourth of the total annual output of the States. The ore mined is very rich, containing over 30 per cent. lead, and 30 ounces silver per ton. Its richness enables it to hold its own, notwithstanding its great inaccessibility to markets and to fuel. It is partly smelted in Salt Lake City, and partly in Chicago, Illinois.

Missouri and Kansas form the next important lead district. The ores contain no silver, but they are able to hold their own in competition with argentiferous ores, owing to their nearness to markets and cheap fuel.

Nevada was, up till a few years ago, the principal producer of lead, but the output is now not more than 30 per cent what it used to be.

### Zinc.

Zinc is produced to the extent of about 30,000 tons yearly. Upwards of 10,000 tons a year are imported. The ores are raised in New Jersey, Pennsylvania, Wisconsin, Illinois, Tennessee, Missouri and Kansas. They are smelted at Jersey City, Bergenport and Newark, New Jersey; Bethlehem, Pa.; La Salle and Peru, Illinois; St. Louis and Rich Hill, Missouri; and at Le City, Pittsburg and Joplin, Kansas.

Fifty per cent. of the smelting is done in Illinois. At one large works in that state the sulphurous fumes, produced in the preliminary roasting of the ores, are

used for sulphuric acid making. The ore is roasted in a furnace having six beds, along which it is moved mechanically.

The kind of furnaces, used for the distillation, are principally modifications of the Belgian furnace. The application of Siemens' regenerative furnace has been adopted in some works.

Meeting held Jan. 8th, 1884.

MR. B. S. PROCTOR IN THE CHAIR

# DISCUSSION ON DR. DIVERS' PAPER ON THE RECOVERY OF SULPHUR FROM ALKALI WASTE, READ AT THE NOVEMBER MEETING.

MR. JOHN PATTINSON: I think the paper is interesting, and contains a number of new facts in chemical science, which the author appears to make out very clearly. It is valuable, inasmuch as it will prevent future investigators from going over the same ground again, although its practical application is not at present very obvious. Indeed, in the present state of the Leblanc soda process there seems no prospect of success for any process of sulphur-recovery depending on the oxidation of the waste, and alkali makers will not have much heart to experiment with such processes.

MR. F. S. NEWALL: Although, as Mr. Pattinson says, there may be no prospect of success for *oxidation processes* of sulphur recovery, yet I think that the question of making use of the sulphur is one which every alkali maker ought to take up. It is just by attending to points like these that the Leblanc process can continue to hold its own against the ammonia-soda process. After all, the difficulties in the way are not so very great; and if one or two alkali makers were to stick to the Schaffner-Helbig process as Mr. Chance has done at Birmingham, and as we are now doing at Washington, I think a satisfactory solution of the problem would soon be arrived at. I do not wish to make any numerical statements as yet, because the process is still in its infancy; but we have had it continuously at work for more than a year now with very satisfactory results, and I hope that a longer experience of the process will enable us to state those results in the form of well-ascertained and reliable numerical facts.

# REDUCING ACTION OF COKE ON NITRIC ACID DISSOLVED IN SULPHURIC ACID.

BY G. LUNGE.

SOME time ago Naef and myself (in a paper on the reactions in the sulphuric acid chambers, "Chemische Industrie," January, 1884; the original at length has been abstracted in the "Journal of the Society of Chemical Industry," December, 1884, p. 633.) called attention to the remarkable fact that the "nitrous vitriol" of the Gay-Lussac towers, except in a totally abnormal state of the chambers, never contains any nitrogen compound except nitrous acid (of course in the state of "chamber crystals" or nitrosyl-sulphuric acid), even if the gases on entering the tower had contained considerable quantities of nitrogen tetroxide, which ought to have produced nitric acid along with nitrous acid. This fact had been previously noticed by myself and by several other observers, but it had never been established before with such certainty, and been placed beyond any doubt by contemporaneous observations of the gases and the vitriol, with the aid of the most improved

analytical methods. Some of the previous observers had explained it by the assumption that the sulphuric acid of the Gay-Lussac tower, when acting on a mixture of  $N_2O_3$  and  $N_2O_4$ , absorbs only the former and allows the latter to escape. My direct experiments (comp. "Journal of the Society of Chemical Industry," 1882, p. 107) had proved that explanation to be untenable, by showing that sulphuric acid, even at a specific gravity of 1.78, easily and completely absorbs  $N_2O_4$ . Still it might be thought that gaseous mixtures, containing extremely small quantities of nitrogen compounds, the absorbing action of sulphuric acid on  $N_2O_4$  might be less than on  $N_2O_3$ , although I must confess that I could not see any reasonable explanation of such a state of things. Unfortunately, it is hardly possible to work on a laboratory scale with a gaseous mixture containing as small a quantity of nitrogen compounds as chamber exit gases, so that I had to renounce a direct solution of this question. But it had been pointed out in the paper, quoted at the outset, that the nitric acid produced from the nitrogen tetroxide might possibly be reduced to trioxide by the action of the coke packing of the Gay-Lussac tower, and this I have now proved to be the case by experiments made in my laboratory by Mr. E. Schnyder.

Pure concentrated sulphuric acid was mixed with a little pure nitric acid, and it was established by several analyses (according to Peligot's method as modified by myself) that the mixture contained 0.037273 grams  $HNO_3$  in 1 cubic centimetre, which corresponds to the nitrogen contained in strong nitrous vitriol. The mixture had no action on potassium permanganate. Several portions of 50c.c. of this mixture were brought into contact with 20 grams each of clean, ground-up coke in air-tight flasks and kept for different periods and at different temperatures. At the end of the experiments the acid, which now smelt strongly of nitrous compounds, was several times filtered through glass-wool to remove any particles of coke-dust which might have affected the potassium permanganate on titration. The clear acid was put into a burette and slowly run into a dilute solution of potassium permanganate of known strength, heated to  $40^\circ C$ , till the colour was discharged. Thus the quantity of nitrogen trioxide formed could be found, and it has been calculated in the following table in per cent. of the nitric acid originally present.

Period of Action.	Temperature.	Nitric Acid reduced to $N_2O_3$ , per cent.
1. .... 2½ days	$26^\circ C$ .	13.41
2. .... 8 "	$20^\circ C$ .	61.78
3. .... 1 hour	$20^\circ C$ .	10.85
4. .... ½ hours	$38-46^\circ C$ .	96.71

Hence it is proved that the nitric acid dissolved in sulphuric acid, in contact with coke, is reduced to nitrogen trioxide, slowly at the ordinary temperature, but quickly and practically completely at a slightly elevated temperature, such as usually exists in the Gay-Lussac tower. Whether the reduction takes place directly by the organic substance of the coke, or by sulphurous acid produced by the action of the coke on sulphuric acid, the experiment could not decide.

# SOLUBILITY OF CALCIUM SULPHATE IN SOLUTIONS OF SODIUM AND CALCIUM CHLORIDE AND IN DILUTE HYDROCHLORIC ACID.

BY G. LUNGE.

IT is well known that calcium sulphate is more easily soluble in certain saline solutions (such as potassium nitrate and sodium chloride), and in

hydrochloric acid than in water—probably owing to mutual decompositions, as seems proved by the following experiments, according to which calcium chloride, which cannot decompose calcium sulphate, lowers the solubility of the latter with increasing concentration. Since quantitative data on the above action seem to be still wanting, I had a few of the more important cases investigated by one of my students, Mr. A. Steiner, viz., the solubility of calcium sulphate in differently concentrated solutions of sodium and calcium chloride and hydrochloric acid, both at the ordinary temperature and at the boiling point.

For the experiments at the ordinary temperature portions of 200 c.c. each of the solutions in question, perfectly free from sulphates, were brought into contact with an excess of freshly precipitated calcium sulphate, entirely free from other sulphates, for a space of three weeks, agitating three times a day. As the experiments were made in summer, and the flasks were kept from sun-light, there would be no very great variations of temperature; the final temperature was always noticed. At the end the liquids were poured through dry filters; the sulphuric acid in the filtrate was estimated by barium chloride and calculated as calcium sulphate.

In the experiments at boiling heat the liquids were boiled with an excess of calcium sulphate in flasks provided with a reflux-cooler for half-an-hour, observing the temperature; they were then poured through a dry filter contained in a hot-water funnel, and the filtrate was allowed to cool down in closed flasks so that no sensible change of concentration took place. In the case of NaCl and CaCl<sub>2</sub> the solutions on cooling did not become turbid, so that the estimation of CaSO<sub>4</sub> could be proceeded with directly; but in the case of HCl a good deal of gypsum crystallized out on cooling; hence a portion of the liquid was taken out whilst hot by means of a pipette whose contents had been estimated at the same temperature, and was diluted with water for the purpose of analysing it.

From the experimental results, the following table of the solubility of calcium sulphate has been calculated.

Temperature	Liquid containing per cent. of	100 c.c. dissolve CaSO <sub>4</sub>
21.5 C.	3.53 NaCl	0.5115 grms.
19.5 ..	7.35 ..	0.6129 ..
21.0 ..	11.0 ..	0.7215 ..
18.0 ..	11.78 ..	0.7300 ..
17.5 ..	17.46 ..	0.7369 ..
101.0 ..	3.53 ..	0.4891 ..
102.5 ..	11.18 ..	0.6248 ..
103.0 ..	17.46 ..	0.6299 ..
23.0 ..	3.54 CaCl <sub>2</sub>	0.1225 ..
21.0 ..	6.91 ..	0.0963 ..
25.0 ..	10.36 ..	0.0886 ..
25.0 ..	15.90 ..	0.0754 ..
25.0 ..	16.91 ..	0.0702 ..
101.0 ..	3.54 ..	0.1370 ..
102.5 ..	10.36 ..	0.1126 ..
103.5 ..	16.91 ..	0.1301 ..
25.0 ..	0.77 HCl	0.6405 ..
25.0 ..	1.56 ..	0.8821 ..
25.0 ..	3.06 ..	1.2631 ..
25.0 ..	1.70 ..	1.5312 ..
25.0 ..	6.12 ..	1.6539 ..
101.0 ..	0.77 ..	1.1209 ..
102.0 ..	3.06 ..	3.1780 ..
103.0 ..	6.12 ..	4.6902 ..

Hence the solubility of CaSO<sub>4</sub> in solutions of NaCl increases with the percentage of NaCl, but diminishes with a higher temperature; CaCl<sub>2</sub> diminishes the solubility of CaSO<sub>4</sub> at the ordinary temperature the more it is concentrated, whilst at the boiling point the concentration is immaterial, HCl considerably increases the quantity of CaSO<sub>4</sub> dissolved, both with an increase of concentration and of temperature.

## ACTION OF CHLORATES ON METALLIC EVAPORATING VESSELS.

BY G. LUNGE.

EVERY manufacturer of chlorate of potash is aware that his boiling-down pans are acted upon by the liquors, even when they are free from chlorine or hypochlorite. The clear liquor becomes turbid during the evaporation, and in the case of iron pans deposits a red muddy precipitate. In the case of lead the formation of a mud is not so conspicuous; evidently the lead oxide originally formed decomposes with potassium chloride into caustic potash and lead chloride, at least partially. Usually it is assumed that lead is less acted upon than iron, but the latter is often preferred as being more durable. It seems to be an open question whether cast iron or wrought iron is more suitable for such boiling-down pans; the latter are cheaper for large sizes and more easily repaired than cast-iron pans, but are more quickly acted upon by the liquors.

Since no positive experiments have been published concerning the action of chlorate liquors upon the pans, I have caused such to be made by Mr. A. Deggeler in the following manner.

We provided short pieces of cast-iron, wrought-iron, and lead tubing whose surface could be accurately computed. These were separately immersed for seven hours in boiling solutions—First, of pure potassium chlorate, containing 6.03 per cent. KClO<sub>3</sub> by weight; second, of potassium chlorate, containing 25.0 per cent.; third, of calcium chlorate and calcium chloride, obtained as usual by passing chlorine through milk of lime and boiling till no more free chlorine or hypochlorite was present; this solution was diluted to spec. grav. 1.16. During the treatment the loss by evaporation was always made good by adding fresh water; in the end the solution was filtered from the metal and the precipitate formed, and the latter was well washed.

The action which had taken place could be easily determined in the two first cases by estimating the chloride formed, for the potassium chlorate employed was entirely free from chloride, and according to previous experiments made in my laboratory solutions of potassium chlorate lose no oxygen even by prolonged boiling. Of course it would have been very acceptable if the results could have been checked by estimating the loss of weight of the metal, but this could not be done since part of the oxides formed closely adhered to the metal, whilst another part floated about in the liquor. Neither was it practicable to estimate the increase of weight of the metal by the oxide formed, and in the case of lead this would have led to nothing at all, because some PbCl<sub>2</sub> is formed. But in this case as well as in that of iron it was sufficient to estimate the chloride formed, since it is evidently indifferent whether the chloride present is that of K or of Pb, and the latter remains dissolved in the large bulk of liquid.

In the third case, that of a mixed solution of calcium chlorate and chloride, only part of the liquid could be taken for analysis. The quantity of chloride present was accurately estimated both before and after the experiment, and the amount of action calculated from the increase of chloride.

The quantity of chloride formed served for calculating (a) the quantity of chlorate decomposed which in the following table is put as KClO<sub>3</sub> by that of the metal dissolved, with the, no doubt very nearly correct, assumption that the compounds formed are Fe<sub>2</sub>O<sub>3</sub> and PbO. The results, each of which is the average of at least two well-agreeing experiments,

are all reduced to 1 square metre of metallic surface.

Results of seven hours' boiling of solutions of :

	Metal oxidized grams.	KClO <sub>3</sub> decomposed grams.
I. Potassium chlorate 6.03 per cent. upon 1 sq. metre of cast iron .....	11.25	12.26
" 1 " " wrought iron .....	20.10	21.96
" 1 " " lead .....	61.30	12.76
II. Potassium chlorate 2.50 per cent. upon 1 sq. metre of cast iron .....	21.49	26.90
" 1 " " wrought iron .....	11.90	18.94
" 1 " " lead .....	151.12	29.81
III. Calcium chlorate and chloride spec. grav. 1.16 upon 1 sq. metre of cast iron .....	85.00	92.65
upon 1 sq. mt. of wrought iron .....	95.00	103.55
" 1 " " lead .....	137.70	86.31

From this the following conclusions may be drawn :—

1. All metals employed are acted upon by the boiling liquors treated therein, more so by concentrated than by dilute solutions of potassium chlorate, and most of all by the mixed solution of calcium chlorate and chloride formed in manufacturing. Since the latter solution is boiled down in practice, much further than the strength employed in the above experiment, viz., to about spec. grav. 1.37, its action upon the metals will thus be much stronger than in the series III.

2: The weight of metal dissolved is always smallest in the case of cast iron, by far the greatest in the case of lead, wrought iron holding a middle place, but being in the series III, not much worse than cast iron. If we consider that the calculations from the chloride formed are made from pure iron, but that cast iron only contains 90 to 93 per cent. of such, the difference between cast and wrought iron is still further reduced.

3. The weight of chlorate destroyed does not differ very materially whether cast iron or lead are employed; in the series I. and II. it is slightly in favour of the former, in the series III. of the latter.

4. Since in any case the quantity of chlorate destroyed is not essentially less in the case of lead pans than in that of iron pans, but the loss of metal dissolved (as well as the cost of firing and repairs) is much greater with lead than with iron, boiling-down pans made of iron are preferable to leaden ones. According to the practically most important series of experiments, number III, there is no essential difference in respect of action between cast and wrought iron.

## HOW SELENIUM GETS INTO HYDROCHLORIC ACID.

BY EDWARD DIVERS, M.D.

*Professor of Chemistry in the Imperial College of Engineering,  
Tokio, Japan.*

KIENLEN appears to have been the first to draw attention\* to the occurrence of selenium in commercial hydrochloric acid. It has been also the subject of notices by Hart† and Davies.‡

The selenium comes, of course, from the sulphuric acid used in making the hydrochloric acid, and is to be seen, partly or wholly, in the elemental state, suspended in the hydrochloric acid solution. But it is wrong to suppose that selenium volatilises in this state during the treatment of the salt with the seleniferous sulphuric acid, and that it then comes over when the heat in the decomposing pan has increased to dull redness (Kjellen).

Selenium comes off with the first portions of hydrochloric acid gas, and while the mixture is therefore relatively cold, and would still do so even if the mixture were colder than in practice it is. The escaping gas is itself apparently colourless, but it colours a concentrated solution of hydrochloric acid yellow. With water both the gas and the yellow solution give a red precipitate of selenium.

The selenium distils over in the form of selenium selenochloride,  $\text{Se}_2\text{Cl}_2$ , and this decomposes when it meets water, into elemental selenium, selenious acid, and hydrochloric acid. Selenium selenochloride is hardly volatile at ordinary temperatures by itself, but it rises readily with hydrochloric acid gas, probably as a colourless compound,  $\text{HCl}(\text{Se}_2\text{Cl}_2)$ . It was this volatilisation of selenium which led me to detect selenium in Japanese sulphuric acid, before Kienlen, or anyone else, so far as I know, had published any statement of its occurrence in some commercial hydrochloric acids. My former pupil, Mr. Shimosé, M.E., has published in the *Chemical News* his observation of the liability to loss of selenium in analysis by the volatilisation of selenium selenochloride from a hydrochloric acid solution, when selenium has been dissolved in that acid with the help of bromine used too sparingly.

When the selenium is in the sulphuric acid in the form of dioxide, there seems to be present always enough reducing matter—bromides, sulphur dioxide, the iron of the pan, etc.—to cause its reduction (Hart). When it is in the form in which it dissolves in sulphuric acid, that is of sulphoxide,  $\text{SeSO}_3$ , as well as after its reduction from its oxide, it reacts at once with hydrochloric acid in the manner described by Mr. Shimose and myself,§ and forms the selenium selenochloride, which then volatilises:—

Where the selenium selenochloride is acted upon by water in absence of sulphur dioxide, part of the selenium as already mentioned remains in solution:—

But in presence of sufficient sulphur dioxide all the selenium becomes free :—

Even where, as is more usual, the selenium selenochloride has been formed by the combined action of hydrochloric and sulphuric acids as shown by the uppermost of the preceding equations, the selenium chloride distilling over condenses so much quicker than the sulphur dioxide, simultaneously formed and present with it, so as to give at first a yellow solution, if only very little water, or the strongest hydrochloric acid is present. Thus the selenium comes over with the first portions of gas from a batch, and not with the last portions as hitherto supposed.

The remainder of the Meeting was devoted to the exhibition of novelties in apparatus, etc., and the reading of short notes.

Mr. LARKIN, of the St. Bede Chemical Company, exhibited and described plans of his new mechanical decomposing furnace now in use at the St. Bede Works at Jarrow. A detailed description of the furnace and results of its working will probably be given at a future meeting of the Section.

Mr. D. CRAWFORD, of Langdale's Manure Co., sent for inspection an ordinary red brick which formed part of the lining of a Glover Tower. After three years' constant work the tower had to be emptied in order to renew the saucer, and the bricks

\* *Bul. Soc. Chim.* 1882; *Ch. News*, 46, 66.

† *Ch. News*, 48, 193.

† *Z. S. Ch. Ind.*, 2, 157.

were found to be quite perfect and unacted on, although they were common red bricks, and not fire-bricks. The brick in question was still nearly perfect, though it had been exposed to the air for three months after being taken from the tower.

Mr. J. B. PAYNE exhibited and described Stead's gas-sampling apparatus, Arnold's Bath for colour-test, and Ballard's Chlorimeter; also some samples of "artificial silk," a new filament produced by pressure through a die, from pyroxylin, the invention of Mr. J. W. Swan.

Mr. T. W. SWEET exhibited a small ambulance box, containing lint, bandages, restoratives, etc., similar to those distributed throughout Messrs. Tenuants' works at Hebburn, in case of accidents.

### STARK'S RESERVOIR BURETTE.

In chemical works laboratories where many titrations of the same kind have to be made, the ordinary reservoir burette, as figured in several text-books, and in which the reservoir for the standard solution is placed at a level higher than that of the burette, is found in practice to be very convenient, as well as to effect a considerable economy in time. Such an arrangement, however, necessitates the reservoir and burette being fixtures, and this in all laboratories cannot without inconvenience be done. The accompanying sketch shows a burette which, while

retaining the advantages of the arrangement above referred to, has the additional advantage of portability. To fill the burette, the reservoir *a* is raised in one hand while the clip *b* is opened by the other. The solution having been adjusted to its proper level, the clip *b* is closed, and the reservoir returned to its place on the stand. It will be noticed that the solution enters the burette by a tubulure at bottom. In introducing this pattern some five years ago, I was not without fear that it was an arrangement which would tend towards increased breakage; such has not been the case, however, as out of a number of burettes of this pattern in daily use under my own observation, during that time not one of them has been broken at this point.

Next, as regards the protection of the standard solution used. It is of course desirable in all cases that standard solutions should be kept as far as

possible out of contact with the dust and various fumes to which the air of most works laboratories is at times subject. For this purpose a small wash-bottle *c* is a very simple and very efficient arrangement. In it is placed a little of the solution contained in the reservoir, or such other solution as may be considered more suitable; and, as the whole of the air entering the reservoir has first to pass through this wash-bottle, any deleterious action that might result to the solution takes place therein. Taking the case of arsenite of soda solution used in testing bleaching powder, a little of this solution is put into the wash-bottle, and so efficient is this arrangement that in a laboratory, daily under my own observation and situated within less than thirty yards of one of the largest bleach plants in the country, no variation in the strength of the solution is found to take place during periods of between three and four months. Never less than a three months' supply of this solution is made up at one time in the ease I refer to. A safety tube *d* prevents the solution in the wash-bottle being forced out should an expansion of the fluids and air contained in reservoir and burette take place. Where perfect freedom from carbonic acid is required, as in the case of a solution of Baryta water, the wash-bottle can be supplemented by soda-lime tubes as recommended by Dr. Lunge.

MR. A. M. CHANCE IN THE CHAIR.

## A VISIT TO THE OIL FIELDS OF PENNSYLVANIA.

Communicated to the Birmingham and Midland Section  
December 5, 1884.

BY WILLIAM A. TILDEN, D.S.C., F.R.S.,

Professor of Chemistry in the Mason College.

LIKE any other English people I found my way this last summer across the Atlantic to the meeting of the British Association at Montreal, and returning homewards through the United States I found time to visit some of the chief oil regions of Pennsylvania, and some of the refineries. Thanks to the kindness of several friends, I was liberally supplied with introductions, which secured for me a most courteous reception, and the best opportunities of profiting by the visit. Although I have nothing new to commu-

minate, it occurred to me that an account of this remarkable industry might be interesting to some members of the Society.

The history of the discovery of oil in the United States has been often recited. It is enough, therefore, to say in this place that petroleum was long known to the Indians, who collected it from some of the streams and from the surface of the water of the

lakes. In 1859 about 2,000 barrels, a quantity far larger than had ever been previously obtained by the rude process of skimming the water on which it was observed. A demand for the oil for burning in lamps soon sprang up, and new wells were sunk in the same district. In 1860 the yield was about 500,000 barrels, in 1861 it was over two millions, and in 1862 it amounted to more than three millions of barrels. At

FIG. 1.

Seneca lake. The product thus obtained achieved some notoriety as a patent medicine, under the name of Seneca or Genesee Oil. In 1859 the idea arose of boring into the rock in the hope of obtaining a better supply of this medicinal oil, and the first well was sunk near Titusville, a town on Oil Creek, which was the name given by the early settlers to a small stream running into the Allegheny river. This first well pro-

duced in 1859 about 2,000 barrels, a quantity far larger than had ever been previously obtained by the rude process of skimming the water on which it was observed. A demand for the oil for burning in lamps soon sprang up, and new wells were sunk in the same district. In 1860 the yield was about 500,000 barrels, in 1861 it was over two millions, and in 1862 it amounted to more than three millions of barrels. At

the present time the total product of the United States probably amounts to some forty millions of barrels, whereof more than one-fourth is exported to Europe. The most important oil regions of the United States lie in Pennsylvania, and part of the State of New York, occupying an irregular band of country some 150 miles long, by perhaps 10 to 20 miles wide.

Other oil fields of less importance occur in Ohio, Western Virginia, and Ontario on the Canadian side. In Pennsylvania the oil-bearing rocks belong to the Devonian system, below the carboniferous series, and the oil is not found in contiguity with beds of coal or shale, but in cavities, and dispersed through various porous sandstones. On boring into the sandstone the oil often rises to the surface from a considerable depth, or is even projected upwards into the air by the pressure of the gas which accompanies it. Many of these spouting or flowing wells have been struck, but the flow is generally intermittent, and rapidly declines. The oil is usually attended by more or less salt water.

Those who can look back twenty years can remember the intense excitement which ensued upon the discovery of oil in the United States, and the rapidity with which fortunes were often made and spent. Untaught by experience of what then so frequently happened, speculators continue to rush into the market

effect of the opening of a well in a new district upon the market may be mentioned the well at Butler, which in August last was running some 700 barrels a day. The discovery of this well caused the price of crude petroleum to drop suddenly from about a dollar to 70 cents a barrel, and no one could tell what might happen next.

The Bradford field is the most extensive at present known. Discovered in 1875, and covering some 400 square miles, it continues to be very productive. In 1880 the output amounted to about five-sixths of the yield of all Pennsylvania. The town possesses many substantial buildings, a busy petroleum exchange, and contains upwards of 10,000 inhabitants.

The course of my own journey took me from Pittsburg by the line which follows the Allegheny river to Oil City. A great deal of business is done on the exchange at this place, and the head office of the United Pipe Lines is there; but very little, if any, oil is now got from the wells, and the "derrieks" stand in black

FIG. 2.

as wildly as ever; and there is probably no commodity in the world, the price of which is liable to such exaggerated fluctuations as petroleum. As an example of the sort of excitement which follows upon the discovery of a new field, the case of the Cherry Grove district may be recalled. In May, 1882, this region was covered by a dense forest, almost without human inhabitant. A well was bored, apparently at random, and oil obtained in abundance. Thereupon boring was carried on in every direction. In about two months several hundred wells were sunk; near upon 10,000 people gathered together, and two small towns, Farnsworth to the north and Garfield to the south, sprang into existence. But the yield of oil soon began to decline, and by the following spring the majority of the wells were abandoned. As an instance of the

decay upon the hill sides. From Oil City through Tidioute, Warren and Kinzua, and thence by the narrow gauge line over the hills to Bradford, I passed through some of the most interesting districts, amid pretty country covered for the most part with forest.

The process of boring a well is accomplished in the following manner:—An open timber frame about 70 feet high, called a "derrick," (see fig. 1, p. 35) is rigged up on the spot for the purpose of raising the boring tools. The latter (see fig. 2) consist of several iron rods screwed together, and terminated by the "bit," with its sharp auger-shaped extremity, the whole being lifted up when required, and let down by a rope which passes over a wheel at the top of the derrick, and round the large windlass or "bull-wheel" at the bottom. The tools are set to work by a small engine, which is afterwards

used if necessary for pumping. The pulverised rock is removed every few feet by means of a "sand-pump," and when a depth of some three hundred feet has been reached a wide iron tube or casing is introduced in order to keep water out of the well. When the drill has penetrated as far as the oil-bearing sand, the well tubing, about two inches in diameter, is put in, and the space between it and the bottom of the casing is fitted in by a bag of linseed, which is forced down into position, and soon swells so as to form a water-tight joint. The wells vary in depth from 600 or 700 feet to 1600 feet, and each one costs from 3000 to 4000 dollars. As already mentioned, on striking the oil sand, the oil is often projected from the boring with considerable force into the air, but if not, it requires to be raised by a pump. This is of the sim-

diameter, and surmounted by a cupola. (See figs. 3 and 5). The iron tank cars still convey a considerable quantity of oil to market, not direct from the wells, but from certain centres to which it is brought by the pipes. The whole of the work, both of storage and transport, in Pennsylvania, is undertaken by two companies, of which the United Pipe Lines is by far the larger. The oil from the private tanks at the wells is run through pipes by gravitation into the great storage tanks situated in the nearest valley. Scores of these are to be seen in the neighbourhood of Bradford and Olean, and they give a feature to the landscape even more remarkable than the derricks themselves. Fig. 4 gives a view of the pumping station and tanks in the valley at Colegrove, McKean County

FIG. 3.

FIG. 4.

plest description, consisting of a long jointed rod, with a short cylinder at the extremity, provided with a valve opening upwards. As the oil is raised, it is pumped into a wooden tank standing near the well. When the well-owner desires to dispose of the product of his well, he sends for the agent of one of the companies that undertakes the transfer of the oil from the wells to the great storage tanks, or to the refining centres. The latter are situated at Cleveland, Buffalo, Oil City, and near New York, the tendency being to concentrate the refineries upon the seaboard. The oil then at the well, after being gauged by a stick, is drawn off, and a certificate handed to the proprietor crediting him with the amount run off, less a small allowance for water and loss. The conveyance of the crude oil is now a very simple matter, being accomplished almost exclusively by the pipe lines. In the earliest days of petroleum the oil was carried in barrels, but as this was both an inadequate and expensive plan, large covered wooden tanks, borne on railway trucks, were employed. But these in their turn gave place to iron tanks shaped like a cylindrical boiler some 25 feet long and 5 or 6 in feet

The tanks are huge drums of sheet iron, the older ones containing about 25,000 barrels. They are now generally made of larger capacity, being about 35 feet in diameter, 35 feet high, and hold 35,000 barrels. (A barrel=42 galls.) From the producing districts the oil is driven by powerful force pumps through the mains (4-inch iron pipe). At a distance of 20 or 25 miles it is received in a tank similar to that from which it was drawn, and is again propelled forward by pump to the next station, and so on to the end of the line. The longest lines are from Olean, on the north of the Bradford field to New York, about 300 miles, and altogether the United Pipe Lines own about 3000 miles of pipes, which spread as a network over almost the whole of the oil fields of Pennsylvania. The magnitude of the business they carry on can be inferred from the official statement of the assets and liabilities of the National Transit Company on 30th June last, from which it appears that the oil then in custody of the Company amounted to about 38½ million barrels, or more than 1,600,000,000 gallons.

The natural petroleum from the wells varies a good deal in density and composition, but with one or two exceptions, it is bulked in the storage tanks, and the price is independent of quality. The material operated upon by the refiner is therefore tolerably uniform. Distillation is conducted in iron stills of 1,200 or even 1,500 barrels capacity fired by coal. The Standard Oil Company are by far the largest refiners, having establishments at Cleveland, Pittsburgh, New York, Philadelphia, and in fact at all the chief refining centres.

At their works in New Jersey, not far from New York, the following figures were given me as representing approximately the results of the distillation. The oil in the tanks at common temperatures, and especially in summer time, evolves a good deal of gas, and more is given off on first applying heat. The first condensable distillate or "naphtha," including gasoline, benzoline, and heavier "benzenes" varies from 6 to 15 per cent. The burning oil, divided into two qualities, amounts to 75 to 80 per cent, and the

Europe, as candles are but little used in America, and other applications for it are limited. The burning oil is further refined by agitation with a little sulphuric acid, the agitation being effected by means of air blown in at the bottom of a deep tank. The acid is separated, the oil washed with water and a little soda, and settled. It may afterwards be bleached, if so required, by exposure to sunlight in a glass-roofed tank.

At the New York refinery of the Standard Oil Company, the cooperage, turning out 8,000 finished barrels a day, is one of the most interesting departments of the works.

It was not my fortune to see a fire, though as may be imagined these catastrophes are of common occurrence, not only in the refineries, but in the field. The crude oil in the storage tanks continually gives off hydrocarbon gas, and when a tank is struck by lightning, the gas is frequently inflamed, and so the oil ignited. In order to prevent communication from one to another, each tank is isolated as much as possible by a dry ditch and bank which surrounds it. When a tank catches fire, a cannon is sent for, and shots are fired at the lower part of the tank so as to make holes and allow the oil to escape. If this is not done, there is risk of the oil boiling over, and setting fire to other tanks near.\*

Fig. 5.

residue of 8 to 10 per cent. by separate distillation yields lubricating oil. The oil is heated in stills which hold about 250 barrels each. It begins to boil at about 650° F., and a residue of nearly 20 per cent. of coke is obtained. The latter is burnt under the stills.

For the production of paraffin wax, certain portions of this distillate are cooled by the aid of ammonia freezing machines down to a temperature of 22° F. It then becomes pasty from the separation of scaly crystals of paraffin. These are pressed by hydraulic presses in a room the temperature of which is about 40°, or very little above freezing point. The cake thus obtained is remelted and pressed again at a temperature as near to 80° F. as possible, the room being heated in winter by steam. The wax is not perfectly white, and its melting point is about 126° F. Only one quality is made, and it is wholly exported to

\* THORN CREEK, December 24.—The burning well belongs to the list of sensations which the Thorn Creek district has furnished the Oil Region. Many visitors have been attracted here by it, and all day an admiring crowd lingers in the vicinity. The well is flowing about 2,500 barrels a day, or 100 barrels an hour, and this enormous amount of oil is shot from the top of the casing head in a steady stream, and with a velocity which is like the rush of a cannon ball. For several feet above the top of the casing head there is no flame, owing to the speed with which the gas and oil come from the well, and for over fifty feet up the course of the stream of oil and gas can be marked through the flame before it is lost in the fire. Were it not blazing the oil would shoot in a solid stream over 100 feet high; but now it is a whirling column of white fire for the first 100 feet, and above this red billows of flame roll up 75 feet higher before its fiery colour is lost in the black rolls of smoke. At night the fire lights up the surrounding country for miles, and on Monday night one could see to read print by the light of the fire a mile and a half away, while the pipe line gaugers all over the district can see to do their work by it. Its heat is not so great near the ground as might be imagined, but can be felt best part way up the hill. One gets the best view of the fire from the plank road near the McBride well. From this point, early in the morning, just as daylight begins to creep over the hill, the sight is magnificent. The base of the well is a little higher than the point of observation, and the whole column of flame reaching 175 feet in the air, is brought into strong relief against the dark background of the hill beyond. Nearly every one who has heard of the fire or seen it, has some theory of extinguishing it. But few of them consider the force they have to contend against. The oil and gas coming from the casing head would play with tons in weight as if feathers. Compared with this giant the burning well on 617, Cherry Grove, was a pigmy. A few days since one of the workmen approached the flame near enough to touch the stream with the end of an iron sucker-rod; but scarcely had it touched it before the rod was sent whirling up and outward as if it had been the merest wooden splinter. Messrs. Ross and Bredin have been endeavouring to extinguish the flames. Mr. Ross brings to the work his experience in extinguishing the burning well at 617. His apparatus consists of a piece of casing standing upright, and connected at the base with two lines of casing leading away from the well. The idea was to drop the end of the upright piece of casing over the casing head, and allow the stream of oil and gas to shoot up out of the end of it. This was provided with a valve, which, when proper connections had been made with the other casing lines to tanks, was to close and turn off the stream feeding the flames, and turning the oil through the lead off lines. The men while carrying this apparatus to the fire were to be protected by sheet iron screens and umbrellas held before them. Several attempts were made last night and to-day to get the apparatus over the fire, but the force of the stream and the heat have so far baffled all efforts. When this well caught fire on last Friday, December 19th, it was producing 600 barrels a day. Since burning its production has increased until on Sunday and Monday it was estimated to be flowing at the rate of 3,000 to 1,000 barrels a day, and to-day is probably making 100 barrels an hour. It is the theory of many in the field, and it may be the correct one, that the burning of the well has created a suction on the sand which is drawing the oil from the other producing wells. The same wells which were producing 325 barrels an hour on the morning of the day that Fisher, No. 8 caught fire, were producing 175 barrels an

It does not appear to be the custom to employ trained chemists in the oil refineries, and perhaps the necessity for high scientific skill is not very apparent in an industry such as this which has shaped itself to a settled routine. But I was not quite prepared for the ignorance which seems to prevail generally as to the nature of the material. I was told more than once that aniline colours were made from the oil, and I observe in a popular article in the "Century" for July, 1883, a statement to the same effect. I could get no further information on the subject.

In England and in Europe generally the quality of burning oil is determined by some variety of "flashing" test, that is by observation of the temperature at which the oil emits inflammable vapour. The Americans use a "fire" test with the same object. Their test consists in noting the temperature at which the oil itself catches fire.

that region in common with others in which mineral oils are obtained. This gas consists of marsh gas, accompanied with small quantities of its homologues in vapour. Sometimes hydrogen is also present in appreciable quantity. The following table, which gives the composition of several specimens, is extracted from the Report of the Committee on Natural Gas of the Engineers' Society of Western Pennsylvania.

Formerly the gas was regarded rather as a nuisance, and when a man drilling for oil got only gas, he considered himself very unlucky. But opinion on this matter is changing, and in Pittsburg and the neighbourhood the gas is being applied extensively for all kinds of manufacturing operations as well as for domestic purposes. I visited the Edgar Thompson Steel Works at Bessemer, and the Plate Glass Company's Works at Creighton, near Pittsburg, in both of which natural gas was the only fuel employed. The blast furnace alone is supplied with coke, but

No account of the old regions of Pennsylvania would be complete without a reference at least in passing, to the great supplies of natural gas found in

hour this morning, a decline of 150 barrels an hour, or of over one half since the day previous to the fire. Connors No. 1 has stopped entirely, while the stoppage of Phillips No. 5 undoubtedly causes Fisher No. 1 to hold up better than the others. Whether the theory that the burning well is drawing from the others be correct or not, it is accepted by most of the fieldmen and the operators in the vicinity, for those having wells near Fisher No. 5 have added \$750 to the sum offered to any one who will extinguish the flames. Extract from the *Old City Derrick* newspaper, December 23, 1881.

there appears to be no other process in operation among the industries carried on round Pittsburg to which the gas is not applicable. According to the Report just referred to, no fewer than 150 companies had been chartered up to February last for the supply of natural gas in Pennsylvania, and many more were in process of formation.

The permanence of such a supply is of course a question of supreme importance, but as many of the wells have continued to yield large quantities of gas pretty regularly for many years, there is but little

risk of the supply failing. The pressure at the wells is enormous, being commonly 75 to 100 pounds, and even reaching more than 150 pounds on the square inch. This high pressure, whilst in general a source of trouble, may turn out to be a condition of real advantage. It is necessary in order to burn the gas conveniently and to avoid dangerous leakage from the mains, to reduce the pressure so as to be equal to a few inches of water, and this is found to be most satisfactorily effected by means of a tank governor similar in principle to the ordinary gasometer. But it is now proposed to make use of the pressure of the gas itself by driving it through an ordinary steam engine before it is delivered into the gasometer to be employed as fuel for the purpose of raising steam. If this should be satisfactorily accomplished, the "power" then at the disposal of the manufacturers of Pennsylvania will be cheaper and more abundant than in any country in the world.

## DISCUSSION.

Mr. ENOCH EVANS: I should like to know whether Dr. Tilden had an opportunity of observing anything in the conditions under which petroleum is found which would enable him to offer an opinion as to the origin of the oil existing in the sandstone, and why it is so much more free from sulphur compounds than the products which are obtained by artificial distillation. I should also like to ask Dr. Tilden if he can give the calorific power of the gas which is used for obtaining the high temperature necessary in melting steel.

Mr. CHARLES HUNT: May I ask a question with regard to the pipes used for conveying the oil by the Pipe Lines Company whether they are laid underground or if there is a public road upon which they could be laid. With regard to the natural gas which has been described, I infer that it is of very low illuminating power, being composed of marsh gas, but very pure—that is free from sulphur.

Mr. HORACE BROWN: There is one product from the petroleum which I should like to ask about, and that is vaseline, and from what it is obtained.

Dr. TILDEN: The pipes by which the oil is conveyed are carried partly over the open country, but the mains run chiefly alongside the railway track. I believe a good many of the local railway lines belong to the United Pipe Lines Company or to the Standard Oil Company, the effect being that all the oil produced in a district necessarily passes through the hands of the representatives of one of these companies, and they work the thing between them.

One speaker has enquired why petroleum is free from sulphur. The answer to that is that petroleum is not always entirely free from sulphur, and as to the origin of the oil, though I have no special views upon the subject, I may mention that the idea of petroleum being a product of distillation is not the only available hypothesis. Mendeleëff has suggested that these natural stores of hydrocarbons may have resulted from the action of steam or water upon masses of carbides of iron. As to the illuminating power of the natural gas, it is of course generally very low, but it may be improved to any extent by mixing with it a small quantity of the vapour of the lightest naphthas got in the distillation of the oil. The heating power is not to be wondered at when we consider that producer gas which contains no more than about one-third of its volume of combustible ingredients, the rest being carbonic acid and nitrogen, is capable of yielding any desired temperature. The natural gas consists wholly of combustible hydrocarbons, and is therefore capable of doing all that producer gas can do and more. The one practical difficulty is the regulation of the pressure.

Notices of papers and communications for the Meeting to be sent to the Local Secretary.

The following is the business for the next meeting of the Section (Tuesday, Feb. 3rd):—1. "Iodine Absorptions," by Professor Mills; 2. Professor Mills will open a discussion on "The Proposed Rivers' Pollution Bill."

*A meeting of this Section was held in the Rooms, 207, Bath Street, on Tuesday, 6th January, at 8 p.m.*

MR. E. C. C. STANFORD, IN THE CHAIR.

THE minutes of last meeting having been read and confirmed, the following papers were read:—

## ON A NEW FORM OF GAS THERMOMETER.

BY GEORGE BEILBY.

THE gas or air thermometers hitherto described, may be referred to three classes, typified by certain well-known instruments; these are:—First, the air thermometer of Regnault; second, the differential thermometer of Leslie and Rumford; and third, the air thermometer of Berthelot. Regnault's thermometer has a well-ascertained value for the accurate determination of all temperatures above 0°, and below the softening point of glass. Each determination involves a somewhat lengthy cycle of operations, the instrument is therefore inapplicable to the determining of rapidly changing temperatures. Leslie and Rumford's differential thermometer, in which two air thermometers connected by a U-tube containing sulphuric acid or other liquid, work against each other, is chiefly of use for the observation of minute differences of temperature. In Berthelot's air thermometer changes of temperature are measured by changes of pressure indicated by a mercury gauge.

The physical effect of temperature on gases being expressed either in terms of volume or of pressure, instruments of the first class may be called *volume* thermometers, and those of the third class *pressure* thermometers. In the former, changes in the volume of the enclosed gas at constant pressure are measured, in the latter, changes of pressure with constant volume. Instruments of the differential class occupy an intermediate position as both volume and pressure are changed under variations of temperature.

About a year and a half ago, having felt the want of a trustworthy instrument for the rapid measurement of temperatures above the range of the mercurial thermometers, I began a course of experiments with the object of constructing such an instrument if possible. These experiments, carried on in the intervals of other work, have lasted till now and are not yet concluded.

The simplicity of Regnault's air thermometer made it a most excellent starting point for my purpose. To this instrument it was necessary to add some appliance by which the gas expelled from the vessel exposed to an unknown temperature could be rapidly and, if need be, continuously measured at constant temperature and pressure.

Fig 1 shows such an arrangement, being an adaptation of a form of apparatus frequently used in gas analysis. From the bulb or expansion vessel *e*, a tube *c* of relatively small cubic capacity is led to the graduated cylinder or measuring tube *m*, which is connected at its lower end with another perpendicular tube *t* by the fork piece *f*; these tubes are connected by a flexible tube *i*, with the reservoir *r*, which can

apparatus for use, the stopcock *s* is opened and the level of the liquid in the tubes *m* and *t* is brought to the zero point, while the bulb *e* is immersed in melting ice. The temperature of the tubes *m* and *t* must be carefully kept at the standard temperature for which the instrument is graduated, which may conveniently be 0°, 15°, or 100°. When the zero point is adjusted the stopcock *s* is closed and the instrument is ready for use. It is evident that the adjustment may, with equal convenience, be made at the temperature of boiling water.

The graduation of this instrument is of course quite different from that of an ordinary mercurial thermometer, in which practically the whole mass of mercury is subjected to heat, and expanded at each tempera-

FIG. 1.

be raised or lowered between the upright guides *g*. An outer cylinder *j* surrounds the tubes *m* and *t*, and forms a receptacle for water, steam or other medium used for the maintenance of a constant temperature. The thermometer *d* is used in regulating the temperature. The liquid in the reservoir *r*, and tubes *m* and *t* may be water, oil of vitriol, mercury or a liquid hydrocarbon. The pressure within the tube *m* can be adjusted to the atmospheric pressure of the moment by bringing the reservoir *r* to the position in which the liquid in the tubes *m* and *t* stand, at the same level. In connecting up the

ture. The expansion of the mercury being uniform for equal increments of heat, and the mass constant throughout the range, the degrees at all parts of the scale are equal in size. In the instrument under consideration the mass of gas in the expansion bulb *e* is not constant under changes of temperature, but decreases with every increment. The amount therefore expelled per degree decreases as the temperature rises and the degrees on the scale of the tube *m* become smaller and smaller. Let the capacity of the expansion bulb *e* be 100 vols. at 0°, and let the mass of the gas contained at that temperature be 100, then

the proportions of air retained in the bulb and expelled from it will be as follows:—

TABLE I.		
Temp.	Mass in bulb.	Mass expelled.
0°	10000	0
100	7319	2681
200	5772	4228
300	4765	5235
400	4057	5943
500	3526	6474

The volumes of the quantities of expelled gas as given in the third column will, of course, depend on the temperature of measurement. In the apparatus under consideration the insulation of the expansion bulb *e* from the measuring tube *m* by the connecting tube *c*, makes it possible to keep the former at any convenient temperature, quite irrespectively of the temperature of the bulb. A glance over the table

considerations—first, that the temperature chosen must be maintainable with ease and certainty under the conditions in which the instrument will ordinarily be used; second, that for accuracy in measuring small increments of volume a high temperature is desirable.

Weighing, in the light of the above considerations, the two standard temperatures, the melting point of ice and the boiling point of water at normal pressure, the latter has clearly the strongest claim, as it really fulfils both requirements; it is more easily maintained under all the conditions likely to occur than the melting point of ice, and it insures for the thermometer a much more open scale at high temperatures.

When steam is used in the jacket *j*, water cannot be used in the tubes *m* and *t*. Mercury is used

FIG. 2

FIG. 3

FIG. 4.

shows that at all temperatures above 300° (strictly speaking, above 273°) the mass of air in the measuring tube is greater than that in the expansion bulb; it is evident therefore that absolute control must be maintained over the temperature of the measuring vessel. This is forcibly illustrated by the fact that when the expansion bulb is at 500°, one degree of variation in the temperature of the measuring vessel involves an error of about five degrees on the indicated temperature.

The choice of the temperature for the measurement of the expelled gas is determined by two primary

FIG. 5.

FIG. 6.

instead, and drying tubes are fitted on *m* and *t*, so that only dry air can enter these tubes, as the least moisture condensing on the surface of the glass would cause the mercury to film the glass. The jacket *j* is provided with a loaded valve, by which the pressure of the saturated steam within may be regulated and maintained at 760mm., quite irrespectively of the atmospheric pressure at the time. In this way a uniform temperature of 100° can be maintained round the measuring tube.

When water is used in the jacket *j*, and takes *m* and *l*, 15° is a convenient temperature to use. In this case means must be provided for the circulation of water from a reservoir through the apparatus, to maintain this temperature against external differences. Table 2 and diagram fig. 6 show numerically and graphically the effect on the thermometer scale of the measurement of the expelled gas at three temperatures—0°, 15° and 100°.

TABLE II.

Temp. of Bulb.	Expelled Gas measured at		
	0°	15°	100°
0	—	—	—
100	26.81	28.28	36.63
200	42.28	44.60	57.49
300	52.35	55.23	71.53
400	59.43	62.70	81.20
500	64.64	68.23	88.33

For temperatures above 500° some material other than glass would probably have to be employed for the expansion bulb. The porosity of platinum and other metals at high temperatures has made them quite inapplicable for the construction of pressure thermometers, but I have as yet made no experiments on their suitability for the expansion bulbs of volume thermometers.

During the past year I have made many attempts\* to construct a compact thermometer on the principle of that now described—that is, the measurement at known and constant temperature and pressure of the gas expelled from a bulb or vessel of unknown temperature. Figs. 2, 3, 4 and 5 show the most important of these modifications. In all of the figures, 1, 2, 3, 4 and 5, the same letters are used for corresponding parts: *c* is the expansion bulb, *e* the connecting tube, *m* the measuring tube, *j* the jacket surrounding the measuring tube. Instead of the tubes *m* and *l* containing mercury or other liquid, a piston or plug of mercury *p* is introduced in the tube *m*, to confine the gas and as an index for its measurement. In the instrument shown in fig. 2, the end of the tube *m* is left open to the outer air, and changes of atmospheric pressure affect the pressure and volume of the gas enclosed by the mercury plug. Exposure to the outer air has the further disadvantage that moisture from it condensing on the surface of the glass causes the mercury to film and drag in the tube. Figs. 3 and 4 show two varieties of the next form. To the open end of the tube *m* is attached a bulb or vessel of about 100 times the capacity of the bulb *c*. This instrument having been carefully filled with dry gas of any required tension by means of a mercury pump, the piston of mercury is passed into its place and the tube at the end of the bulb *b* is sealed off. When in use, the bulb *b* being of relatively large dimensions, maintains a nearly constant pressure within the apparatus, the actual variations being calculated and allowed for.

The instrument exhibited, which is similar to that shown on fig. 5, was made eight or nine months ago, and has been used for taking boiling points of paraffin oils up to 450°. It was found that in practical use the mercury index changed its zero point slightly after each journey up and down in the measuring tube. This error under certain conditions was cumulative, and—owing to the construction of the thermometer—

could not easily be rectified without opening and refilling the tubes. This matter was made the subject of direct experiment with a view to the discovery and removal of the cause. At that time the anomalous behaviour of the mercury index could not be explained satisfactorily, but discoveries made since have thrown fresh light on the matter. Under the belief that the alteration of the zero point of the index resulted simply from the passage of gas past the mercury plug, a new form of instrument, shown in fig. 6, was constructed. The mercury column *p* is lengthened to about 2 inches, the tube *m* is made of extra length and is sealed at the top, the bulb *c* and tube *m* are filled with dry gas at a tension slightly under that due to the column of mercury *p*, so that, when the instrument is turned perpendicularly with the bulb downwards, the column of mercury passes down in the tube till it is balanced by the pressure of the gas below it; a vacuum being left in the upper part of the tube. Changes of volume in the gas in the bulb and lower part of the tube *m* make the column rise or fall in the tube, but, as the pressure on this gas is solely due to the weight of the column, the mere height of the latter does not affect the pressure. After each operation the instrument is inverted so that the column of mercury runs down to the end of the tube, and if any gas has passed the column it appears as a bubble between the mercury and the end of the tube. The tube is sufficiently wide to permit of the bubble being passed up through the column by snarling tapping the lower part of the tube. The ease with which the error may be corrected after every operation adds considerably to the confidence with which the instrument is used.

In making thermometers of this form certain curious facts were brought to light which go far to explain the anomalous behaviour of the mercury column already referred to. I have found that a large volume of gas is condensed or occluded by the mercury or by the glass, or by their combined action.

R. Bunsen (*Chem. Soc. Journ.*, xlv. 146) has shown that air and carbonic anhydride are condensed by glass surfaces, and practical thermometer makers are familiar with the fact that certain kinds of glass cannot be used for making accurate standards because of the amount of gas they occlude, but it is very doubtful if the occlusion or condensation referred to above can be accounted for by the glass alone. I hope soon to publish the results of experiments made specially to determine how and where the occluded gas is retained.

Until the laws of the behaviour of gases in tubes containing mercury are fully understood, some uncertainty will prevail as to the accuracy of the indications of temperature given by the forms of thermometer shown on figs. 2, 3, 4 and 5; but in the meantime they at least form valuable adjuncts to the more trustworthy but cumbersome instrument shown on fig. 1.

## AIR OR HYDROGEN THERMOMETER FOR LOW TEMPERATURES.

BY J. J. COLEMAN.

MR. COLEMAN described and exhibited an air or hydrogen constant-pressure thermometer he had specially devised for taking low temperatures, say, to 300° below zero F. In this thermometer the bulb was about 10 inches long and  $\frac{5}{8}$ -inch diameter, from which proceeded upwards a tube bent at right angles, and then turning downwards into a wider tube graduated and open at the bottom end. The open leg of the instrument was dipped into oil contained in a cylindrical outer tube mov-

\* The author's first published account of this system of thermometry was in the Provisional Specification of Patent No. 3750, dated 22nd February, 1884.

able on a pulley, so that the level of the oil inside and outside the recording leg was maintained constant every time an observation was to be taken, thus eliminating errors from the weight of the column of liquid. The recording leg of the instrument is kept at a constant temperature; in fact, the whole upper part of the instrument, by building round it suitable protecting walls within which the temperature was maintained constant by small gas jets. Each observation of course required correction with a barometric observation. The instrument was graduated in absolute temperatures  $F$ . Thus  $62^{\circ} F$ . was really  $522^{\circ}$  absolute, and the length of a degree at this point was ascertained by comparison with a Kew certified thermometer  $30^{\circ}$  above and  $30^{\circ}$  below. The length of a degree at a fixed point being obtained, it only remained to consider that at half the absolute temperature the degree would be doubled in length, and the intermediate degrees were calculated accordingly.

### TENSION-THERMOMETERS AND PYROMETERS.

BY PROF. W. DITTMAR.

PROFESSOR DITTMAR exhibited a number of manometers made by Messrs. Schäffer and Budenberg, and also one of their "Thalpotassimeters," and explained the construction and working of the last-named instrument. The following is a condensed report of Mr. Dittmar's remarks:—The "Thalpotassimeter" is nothing but a Bourdon manometer adapted to the purpose of thermometry. In the Bourdon manometer the working part is a flat tube of elastic metal bent into the form of a semi- (or more than semi-) circle, the inside of which communicates with the steam (or gas) whose tension is to be measured. If this tension is greater than that of the atmosphere, the tube opens out, because the inside overpressure tells more strongly on the concave than on the (shorter) convex flat inside of the tube; and, as the inlet end is fixed, the other end suffers a displacement, which is the greater the greater the over-pressure inside. If the pressure inside the tube fall below that of the atmosphere, the tube bends in—i.e., its radius of curvature becomes less; and in either case the displacement of the free end measures the positive or negative over-pressure of the gas or vapour inside—in this sense, at least, that any given value of the latter corresponds to a certain definite displacement. This displacement, however, in all cases, is too small to be measured directly; it, therefore, is being magnified by means of a lever and a system of toothed wheels, so that an even small displacement of the pipe-end becomes translated ultimately into a large angular motion of a hand on a dial. In the vacuum and other low-pressure gauges, the pipe is made of brass, as in Bourdon's original instrument; for larger pressures, Messrs. Schäffer and Budenberg use a steel tube, which (as shown by the model exhibited) is fitted to the pipe conveying the vapour (or other gas) without the use of solder or packing of any kind. And yet, being made with, one may well say, *Whitworthian* precision, the joint keeps tight even under an over-pressure of 25 tons on the square inch. It is also worth stating that these pipes (even the brass ones), as long as they are not over-wrought by being used for higher pressures than they are intended for, prove *perfectly* elastic, and consequently consistent with themselves in their indications. Supposing the steam of a boiler to be turned on against a Bourdon gauge, the first effect of course is that its pipe fills with condensed water, and this is an

advantage, because it serves to keep the pipe cool, and the water transmits the pressure as faithfully as steam or air would. Now, the pressure of the steam of a boiler (as the pressure of the saturated vapour of any *pure* substance) is a function only of its temperature, every one temperature  $t$  corresponding to one certain pressure  $p$ ; hence our gauge, although intended to be only that, is really a thermometer; because a glance at Regnault's table would enable one to translate the pressures it indicates into degrees centigrade. It is a thermometer, it is true, only in reference to the boiler which it is attached to. But there is nothing to hinder us from providing the gauge with a special little boiler of its own, and we thus convert it into a "thalpotassimeter," or tension-thermometer, as I prefer to call it, because Mr. Budenberg's designation of his instrument is "Greek"—to me, at any rate. That the tension-thermometer scale is figured and divided so as to give temperature value *directly*, needs not be specially stated. The instrument, of course, is not confined to water for its working liquid. Messrs. Schäffer and Budenberg, in fact, make three kinds—namely: 1st, one in which *ether* is used (for temperatures from about  $100^{\circ} F$ . to a little beyond  $212^{\circ} F$ .); 2nd, one with water inside for the range of temperatures prevailing in steam boilers up to the highest-pressure ones, and even higher up; and last, not least, one with *mercury* inside for *very* high temperatures. When I first heard of these tension-thermometers my impression was that, however it might stand with the ether and water instrument, the mercury one would be sure to live as the pyrometer of the future. It is almost impossible to find a vessel which is gas-tight and retains its volume and form at even a dull red heat; hence the difficulty of constructing a really reliable air or gas pyrometer. The mercury-tension thermometer is relatively independent of these conditions: as long as the mercury vapour does not actually fizz out, and although the vessel may suffer a permanent deformation, the vapour-tension will remain all right, and the temperatures be recorded correctly in the sense of consistency at least—i.e., although, from a certain temperature upwards, the relation between temperature and pressure is unknown, even these higher temperatures are all, so to say, precisely "labelled" by their respective dial-hand readings. So I thought; and great, therefore, was my disappointment when I was informed that it is just the mercury-thalpotassimeters which have failed to give satisfaction. When used constantly for high temperatures (i.e., when employed for what they are made for) the mercury sooner or later *will* come out somewhere, and the instrument become useless. In contrasting the tension-thermometer with the ordinary mercury-thermometer, the speaker pointed out that in regard to potential sensibility, the former is at least on a par with the latter, because it is always easy to find a liquid, the vapour-tension curve of which ascends with sufficient boldness within the given range of temperatures. The tension-thermometer, besides, is not liable to any displacement of the zero. [Its indication, it is true, varies with the pressure of the atmosphere; thus, for instance, the reading *meant* to correspond to  $30 + p$  inches does so only when the barometer stands as 30 inches exactly, it really corresponds to  $29 + p$  inches when the barometer falls to 29 inches. If Budenberg's instrument this does not matter much because he discounts only high tensions at which a plus or minus of even half-an-inch of mercury-pressure corresponds to only an insignificant difference of temperature.] And the *Budenberg* tension-thermometer is not intended for "*haute precision*." Unfortunately for its popularity, it is very expensive: the instrument here exhibited costs, I believe, £4.

# DESCRIPTION OF AN IMPROVED THERMOMETER FOR TAKING HIGH TEMPERATURES.

BY JAMES MURRIE.

THE upward range of a mercurial thermometer is limited by the boiling of the mercury at a certain point, which varies under certain conditions. By increasing the pressure or resistance tending to prevent ebullition, a greater range of thermometric readings can be obtained.

a higher temperature than is possible under normal conditions.

The instrument consists of two vessels in communication with one another by means of a tube of small bore. In one chamber is placed mercury, and in the second chamber alcohol or other elastic fluid. The two liquids—or the mercury and fluid—meet in the connecting stem at the base of a transparent tube, which forms part of the tube connecting the two chambers. The mercury on being subjected to heat expands, and in expanding compresses the elastic fluid, the amount of expansion

## MURRIE'S PATENT IMPROVED THERMOMETER. FOR TAKING HIGH TEMPERATURES.

The apparatus represented by the annexed sketch illustrates one means whereby such an opposite pressure can be generated, and the boiling point of the mercury in consequence raised, the mercury being therefore maintained in a liquid condition at

being observed by means of the transparent tube referred to. The effect of such expansion is to generate a pressure, due to the compression of the elastic fluid, which pressure, re-acting on the mercury in the bulb, is the means of raising its boiling point,

the limit being the strength and rigidity of the apparatus.

The sketch is self-explanatory. A great variety of apparatus can be constructed on these lines, a few of which I hope to bring under your notice on another occasion.

#### DISCUSSION.

MR. COLEMAN: I quite agree with Professor Dittmar that temperatures can be taken by means of pressure gauges quite as easily as by direct measurements by increase of volume of liquid or gas, and also that such methods can be used either for high temperature or low temperatures. In reference to low temperature and the use of liquid sulphurous acid, it must be borne in mind that the sulphurous acid boils at only about zero F., and its use would be limited to temperatures above that point. If you wanted to get a little lower, say minus 100° F., you would require to use liquid carbonic acid; and if still lower you would require to use liquid ethylene or liquid oxygen, and so on; and further, you would require special instruments of such good construction as to be scarcely obtainable—whereas in taking an instrument like the one I have described to you, you not only get your accurate observations down to the lowest point you can possibly take it, but you always get the true thermodynamic scale.

MR. BEILBY: I should like to ask Mr. Coleman if he finds it sufficiently accurate to treat the curve of mass of gas in the thermometer bulb at different temperatures as a straight line. In practical graduation I have always started from zero C., and worked upwards to the higher temperatures, laying down the *continuation* of the curve which may be supposed to start at absolute zero. This curve, from zero upwards, rapidly changes its curvature, and would only approximate to a straight line over short ranges of temperature. Mr. Coleman's method will, I fear, give considerable errors on the intermediate graduation between the two determined points if these are as much as 245 F. apart. The instruments which Professor Dittmar has so clearly described mark a new departure in thermometry. The principle on which they are based is so sure, and, in many respects, so well calculated to produce a sensitive and accurate thermometer, that we must hope that even if at present the instruments under trying conditions fail in respect of trustworthiness, yet the skill and perseverance of the makers will finally overcome the defect. The thermometer is such an important tool to scientific and technical chemists and physicists, that all good workmen will gladly adopt the best and keenest tool that can be supplied to them. My own interest in the subject originated in the deeply-felt want of a high temperature thermometer for use in practical researches on the distillation of paraffin oils at temperatures above the boiling point of mercury. If such an instrument had been ready to hand it would have saved much valuable time, and would have been gladly adopted; but on looking over all of the literature within my reach, I could light on no practical instrument, and I have not been able to hear of any such being in regular use. The *pressure* principle (of gases, not of saturated vapours), so warmly advocated by Professor Dittmar, was set aside on general as well as particular grounds. Notwithstanding the undoubted advantage of having the whole mass of gas always exposed to the temperature to be measured, instead of only a fraction, as in the *volume* thermometer, there always remains the fundamental difficulty of making an expansion bulb and connections which will remain perfectly gas-tight and retain their form and capacity under the com-

bined influence of 500° C. (a temperature little, if at all, short of redness), and an over-pressure of 30 lb. per square inch. It is most probable that this problem in construction will be solved for gases and for saturated vapours simultaneously. The most serious objection to the volume thermometer, that its degrees diminish in size with the diminishing mass of gas in the bulb, is to a certain extent removed in the instruments I have described by the measurement of the expelled gas at 100°; the scale up to 500° is thereby made a fairly open one.

MR. COLEMAN, in reply, said that there could be no mistake about the method of graduating either Mr. Beilby's or his own air thermometer. If once the length of a degree at a fixed point, say 500° absolute, were determined—from the laws of thermo-dynamics, as soon as the temperature became one-half, that is, 250 absolute, the length of the degree would be double, not from the consideration of the curve of expansion of a known initial volume of air, but from the fact that the quantity of air in the thermometer bulb will always vary as the absolute temperature; and consequently, when the absolute temperature sinks to one-half of what it was at the start, the bulb contains twice as much air as at the start, and therefore the degrees on the stem must be double, and so on with any other arbitrary temperature we like to take.

Prof. DITTMAR suggested that the *constant volume* air thermometer, if properly contrived, might prove a handier instrument than the constant-pressure form adopted by the two gentlemen. The Bourdon manometer might be used for the measurement of the tensions; by means of it the ideal constancy of volume would be realized approximately without any trouble.

MR. J. MURRIE: It has already been pointed out that the mercurial thermometer is liable to give wrong indications, particularly for comparatively high temperatures. I find from practice that the tension thermometer is just as liable to give inaccurate indications, due, I believe, to the pressure gauge not indicating the pressure correctly, especially when it is subject to variations of temperature; independent of this I have found it a difficult matter to get two Bourdon pressure gauges, connected to the same generator, to give exactly corresponding indications. Such variations, I believe, render the tension thermometer as liable to being inaccurate as the common mercurial thermometer.

MR. STANFORD: I would like Mr. Murrie to answer one question which has already been mentioned to-night—viz., How the metal stands the action of the mercury at high temperatures?

MR. MURRIE: I have made some experiments in order to see what action the metal had on the mercury and I find that it had literally no action, the mercury always returning to the same starting point.

MR. T. L. PATTERSON, referring to the thalpotassimeters of Schäffer and Budenberg, said: Some years ago he had got one of these to try along with several others to determine the temperature of charcoal kilns. His idea was to put a pyrometer in each kiln to enable the fireman to keep it at a regular heat. At first the temperature that the pyrometer indicated was fairly good, but it soon fell off. He kept it in for several weeks, and at the end of three weeks the indication was about 200° below what the indication ought to have been. The reason for this was doubtless due to the great pressure which the mercury vapour exerted on the heated tube, causing it to expand and enlarge the chamber in which the mercury was held. In this way the pressure gradually fell, and consequently the temperature indication, so that it soon became useless. The falling off in pressure might also be due to diffusion of the mercury vapour through the red-hot walls of the tube, and to a slight leak at the joint,

which even with the best workmanship it was hardly possible to avoid. A graphite pyrometer subjected to the same conditions fell away in the same way, so that after being exposed to the heated gases of the kiln for three weeks the indication fell off 200° to 300° F., and by-and-bye the pointer stuck and would not move at any temperature. The pyrometers were tested by the method of specific heats, in which a platinum or copper ball was placed in the furnace until it had attained the same temperature, when it was quickly removed and dropped into a measured volume of water, in which the rise of temperature was noted by a thermometer. In this way the heat of a kiln was found to be, by copper balls at two trials—

1,359° F., and  
1,352.8° F.; mean = 1,355.9° F.;

while the graphite pyrometer at the same time indicated

1,020° F., and  
1,150° F.; mean = 1,080° F.,

showing a wrong indication of over 275° F. The old copper rod pyrometer on the Daniell principle gave a better indication than either the thalpotassimeter or graphite pyrometer, but it needed to be often corrected. He thought that if any one wanted to get the proper temperature of furnaces, in which such delicate instruments as Mr. Beilby's could not be introduced, no matter how scientifically accurate they might be, the best method to use was that of specific heat, which was not difficult when one got into the way of it. Regarding the ether and water-tension thermometers, he had had no experience; but he feared the great pressure to which they were subjected would soon render their indications fallacious, as he had found with the mercury one. He was not aware that every refiner in Greenock used these. They were not in the refinery with which he was connected. Neither had he found any difficulty with thermometers often breaking, as Professor Dittmar had said. He knew of a thermometer being in a pan for 10 years without breaking, and he did not think any thalpotassimeter would live so long as that. No doubt thermometers did occasionally break, but they were now so well protected that this very seldom happened.

The CHAIRMAN: We are much indebted to Mr. Beilby for bringing before us the very important and almost universal form of air thermometer which he has exhibited; and to Professor Dittmar for showing us these excellent varieties of apparatus from Schäffer and Budenberg—names that are well known in most of our works in connection with pressure gauges. Our thanks are also due to Mr. Coleman for bringing before us what I really think will be the thermometer for registering low temperatures. It seems to me to be almost the only one that is likely to be accurate when you come to deal on the large scale with such temperatures as 200° below zero; and I expect to hear from Mr. Coleman, some evening later on, of very important practical results from this instrument, for I much doubt the accuracy of low temperatures, taken on the very small scale in which hydrogen and oxygen have been hitherto liquefied. We are also indebted to Mr. Murrie for his very ingenious high-pressure thermometer; he expects it to register up to 2,500°; and after what Mr. Patterson has stated about the difficulties of obtaining accurate results by pyrometers (which I think are admitted by every one), we shall look forward to having this instrument brought before us again in the more perfect form which Mr. Murrie has promised.

## Journal and Patent Literature.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

*Improvements in the Construction and Arrangements of Dedicating Machines.* W. A. Dyer. Eng. Pat. 10,816, July 31, 1884.

THE object of this invention is the construction of a vacuum pan or dedicating apparatus in two compartments, so that the operation can be carried on in two stages; to provide means of agitating the material in the interior of the pan; a discharging door between the two parts of the apparatus so that they can be worked independently of each other; a discharging door in the lower part of the apparatus for the finished material; and an intercepting vessel for avoiding the ejection of material from the pan up the vapour outlet pipe. The apparatus is constructed in three pieces, a lower steam jacketed portion, a middle piece similarly jacketed and separated from the lower part by a jacketed deck, and a dome having an intercepting bell in its upper part. The usual outlet pipe to the condenser is provided and also communication pipes between the upper and lower parts of the pan. A vertical shaft having agitators and scrapers in each chamber is also shown passing through the stuffing boxes in each part of the pan. The doors for discharging the material from the upper deck to the lower, and also out of the pan, are worked from the exterior of the apparatus by suitable screws, worms and spur wheels. The usual pressure gauges, safety valves, steam and condensed water outlet cocks are shown. The patentee claims the various devices and their construction as above enumerated, in combination with dedicating machines by seven distinct claims.—C. C. H.

*Improvements in Filtering Machines.* J. A. Crocker, Boston, U.S.A. Eng. Pat. 12,691, Sept. 23, 1884.

THE improved filtering apparatus consists of a casing resting upon trunnions on which it can swivel freely, and which serve, the one for an inlet for water to be filtered, the other as an outlet for the filtered water. The heads of the casing are hollow, that on the supply side conducting the water to the top of the apparatus, and that on the outlet side collecting the water after filtration. The filtering material occupies the central part of the machine placed between two gratings, which keep back the coarser impurities. The filter is cleaned by revolving it upon its trunnions, which changes the direction of the current, and carries the water containing the impurities, arrested by the filter, out by a waste channel. Matter difficult of removal from the gratings is either scraped off by scrapers working through a stuffing box from outside the filter, or it may be removed by the injection of steam. The whole machine and its several modifications and details are covered by 15 distinct claims.—C. C. H.

*Improvements in Calcining Kilns.* J. T. Raynes and B. D. Healy, Liverpool. Eng. Pat. 1,737, Jan. 19, 1884.

THE subject of this invention is those kilns in which gaseous fuel is used, and in which lime, ores, &c., are burned. The gaseous fuel enters the interior of the calcining chamber at its base by means of flues running around the whole chamber, from which ports branch off into the chamber. Below this the furnace tapers to the drawing doors, at the outer end of which are gratings for screening the calcined material passing out of the furnace. The calcining chamber is divided into two or more parts by walls crossing it transversely, and these walls are furnished in their interior with gas and air flues. Cleansing doors and sight holes are also provided in suitable places, and the top of the furnace is mounted with a charging hopper and doors. The furnace is charged and set going with coal or coke in the well-known way, the gas is then admitted, and is brought in contact with the air as it issues into the furnace, the

air during its admission passing through the hot material discharged from the furnace. The patentees claim (1) the construction of a central partition, (2) providing the drawing holes with screens, (3) the construction of twin kilns, each part of which may be worked separately.

—C. C. H.

#### *Improvements in and relating to Evaporating Apparatus.*

H. H. Lake, London. Communicated by A. Vivien and D. R. Dujardin, Lille. Eng. Pat. 2,286, Jan. 28, 1884.

This invention relates to the construction of vacuum pans, and chiefly those of the class commonly known as "triple effect." The improvements consist of supplying the steam to the tubular heating surface by a pipe entering the upper or lower tube plate centrally, inserting a helical partition between the rows of tubes, so that the steam comes in contact with the whole of the tubes, circulating through the apparatus in a spiral form, removing the inert vapours in the tube partition of one pan, by suction, into the tube partition of the next pan, providing means for the removal of the condensed water in the tubes, so that by operating on the end pan of the series, the water in every pan is withdrawn simultaneously, providing a safety apparatus commonly known as "a save-all," formed in the top of the pan by two concentric pieces of tube forming dripping pieces on the central steam supply pipe, so as to prevent the projection of liquid along the surface of the tube; and lastly, in the formation of a condenser, wherein a cascade of water is formed by means of removable projections or trays. The invention and its various details are covered by 11 different claims.—C. C. H.

#### *Improvements in Apparatus for Preventing Corrosion in Boilers and other Metallic Vessels.* J. B. Hannay, Dumbarton. Eng. Pat. 2,927, Feb. 8, 1884.

THE subject of this invention is an improved method of applying the apparatus already patented by the same author for the purpose set forth. Zinc blocks were therein suspended by means of conducting wires in the interior of the steam vessel to the metallic plates forming the shell of the vessel; the salts contained in solution were deemed sufficient to set up electric action. Some waters do not, however, contain sufficient sodium chloride to set up the desired action, and in certain cases the direct addition of the quantity requisite is inadmissible. In such cases the patentee proposes to inclose the "Electrode" in the interior of an impermeable vessel, insulated from its sides, and packed round with crystals of salt; the conducting wire is carried through an asbestos stopper to the plates of the boiler. The patentee claims the application of zinc blocks enclosed as described for preventing corrosion in boilers.—C. C. H.

## II.—FUEL AND LIGHT.

#### *Improvements in the Manufacture of Clay Retorts.* W. D. Chill, Leeds. Eng. Pat. 13,188, Oct. 4, 1884.

THE object of this invention is the production of retorts, to be used in coal gas manufacture, with a glazed interior, so that the carbon produced will not cling to their sides. Whilst the retort is in course of construction, and the clay is in the green state, the interior is faced with what is well known under the name of "porcelain body;" and, when completed, before being fired, a glazing material, of a nature depending upon the clay, is applied over the face of the first coating. The claim is:—Lining the interior of retorts as described so as to produce a glazed surface thereon.—C. C. H.

#### *The Brown-coal of Istria and Dalmatia.* Dingl. Poly. Jouru. 253 (13), p. 531.

LADIN (Annales des Mines) after discussing at length the geology of Istria and Dalmatia, states the results of five analyses of brown-coal. No. I. was coal from the Carpano-valley, taken from the bottom layers; No. II., from

the same place, but after exposure to the air for some length of time; No. III. and IV., from the top layers; No. V., a general average sample.

#### *Improvements in Effecting Combustion of Liquid Hydrocarbons in conjunction with Water, Gas or Steam.* J. H. Selwyn, London. Eng. Pat. 2,160, January 25, 1884.

ACCORDING to this invention liquid hydrocarbons are burnt in a furnace in conjunction with water gas or steam in presence of a substance containing both carbon and iron. In a previous patent (Eng. Pat. 4108, August, 1883) the arrangement of a furnace particularly adapted to resist the action of a continued high temperature, was described, this being capable of expansion and contraction, whilst remaining also to a certain extent airtight. Thus by a careful regulation of the air supply carbon could be continuously formed from the hydrocarbon blown in, and fulfil a condition necessary to effect formation from steam of hydrogen (60%) carbonic oxide (20%) and carbonic anhydride (20%). To secure the constant deposition of carbon the inventor employs plumbago or graphite, which containing both carbon and iron is peculiarly adapted for the construction of furnaces of the above nature. The plumbago or graphite may be introduced into the furnace in the shape of bricks, linings or balls so as to render it possible to decompose the steam with which the hydrocarbon oil is blown in, and so to obtain a temperature of about 3776° F., such as may give the greatest quantity of gas for heating purposes. Iron being present the quantity of hydrogen produced is still further increased beyond the above named proportions, according to the following equation:  $4H_2O + 3Fe = Fe_3O_4 + 8H$ . The construction of the furnace is described in detail in the original specification.—D. B.

#### *Improvements in the treatment of Coke and Peat.* R. Smith Casson, Stafford. Eng. Pat. 1340, January 12, 1884.

To promote the rapid combustion of the carbon of coke or peat, and thereby produce a comparatively clear flame the patentee proposes to soak or otherwise thoroughly impregnate the combustible substances with petroleum or other oils or fatty or resinous substances.—D. B.

#### *An Improved Process for Mixing with Earthy Matter and for Consuming as Fuel, Petroleum and other Hydrocarbons, and Apparatus for Carrying the same into effect.* W. P. Thompson, Liverpool. Communicated by J. Leede of Washington and Granville H. Ouray, Florence, both in the U. S. A. Eng. Pat. 1864, Jan. 22, 1884.

IN carrying out the first part of the invention, an apparatus is constructed consisting of a hopper for holding the granular or powdered material, provided with suitable conveyors for conducting the materials to the mouth of a vessel or furnace, a suitable tank for holding the hydrocarbon, provided with pipes, valves, etc., for conducting and regulating the flow thereof, under a head or pressure to the mouth of the furnace; a suitable blower to scatter and diffuse the hydrocarbon and solid materials and thereby cause a perfect admixture of the two. For carrying out the process of combustion additional means are provided for producing a gas or other jet flame near the mouth of the conduits and blast pipe, whereby the mixed fuel is ignited and consumed as it is scattered by the blast while in suspension. That part of the invention

which relates to the apparatus for feeding, igniting, and consuming pulverised fuel, saturated with petroleum, consists (1) in the combination of an automatic feed, means for producing a blast, and means for producing a jet flame, for igniting the fuel as it is projected away from the feed tube by the blast; (2) in the combination of a blower, a "carburettor" and a series of blast pipes for diffusing the fuel throughout the chamber and suspending it during combustion as well as for supplying oxygen; (3) in the combination of a series of blast pipes for igniting the fuel as it escapes and enters the fire chamber, and (4) in the combination of a series of adjustable pipes and valves for controlling the direction, force, and quantity of the blast without changing the speed of the blower.

—D. B.

*Improvements in Coke Ovens, and in Methods of and Apparatus for Collecting and Utilizing the Products of Combustion from such Coke Ovens.* A. M. Chambers and T. Smith, York. Eng. Pat. 4708, March 11, 1884.

IS the present invention a coke oven of the kind described in a patent obtained by A. M. Chambers in 1879 (Eng. Pat. 5,122) is constructed, its floor being somewhat inclined, so that it slopes gradually down towards the door of the oven. A sufficient number of channels or grooves, either open or covered, is made in the floor, all converging and leading to the lowest point, where they communicate with a pipe, which is carried down and led away to a condensing apparatus. The inventors remove or close the chimney or the flue leading to a chimney described in the specification already referred to, and connect the outer end of the pipe, which surrounds the crown of the oven, to air pumping machinery, by which air can be forced at any desired pressure into the pipe, and thence through the open end of the latter, after having been heated in its passage into the upper part of the oven. Thus the heated air by which sufficient combustion of the coal to effect coking is effected, and the products of combustion are compelled to pass downward through the mass of coal, and thence through the discharge pipe into the condenser. By this arrangement the products of combustion containing tar, heavy and light oils, ammoniacal liquor, and other valuable ingredients, which ordinarily escape by the chimney, and are wasted, are condensed and collected.—D. B.

*Improvements in Apparatus for Extracting Ammonia and other Impurities from Coal Gas.* J. Hanson, York. Eng. Pat. 16, January 1, 1884.

IN order more effectually and expeditiously to wash or purify the gas passing through apparatus constructed to extract ammonia and other impurities from coal gas, a casing of metal plates or enameled brick-work is formed, having man-holes formed therein, in suitable positions, and fitted with covers and connections. The apparatus is fixed vertically, and fitted with a blank bottom, having a stuffing box in the centre, through which pass two shafts, one of them hollow, and the other through the centre thereof, both shafts being stayed by journals in the interior of the apparatus, and supported by suitable footsteps. The shafts revolve in different directions, and are connected with frames fitted with wings at an angle for propelling the gas forward, and around the circumference of each frame is secured a circular brush for the purpose of making a joint between the frames and casing. A basket composed of three or more sections is placed on each frame, each section being fitted with fine wicker-work or strong open fibre, through which the ascending gas must pass. Above the centre shaft a grid is secured, having the bars fixed at an angle of about 45°, and above this grid a layer of porous pumice stone or coke is placed, over which is a cistern with a perforated plate secured thereto, containing a mixture of ammonia and water. The gas having passed through the revolving baskets, grid, etc., is met by a shower of ammoniacal water, supplied from the cistern above, through a valve on to the perforated place, where it is somewhat evenly distributed over the entire area of the apparatus, thereby

keeping the scrubbing material constantly wetted, extracting the ammonia from the gas, the former running away from the basin to a store tank through a pipe connected therewith.—D. B.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Improvements in Processes and Apparatus for Dividing and Distilling Crude Petroleum, and for Refining the Products obtained.* J. C. Mowburn, London. Communicated by the Hallways Process Company, New York. Eng. Pat. 12,498, September 17, 1884.

THE process for the preliminary division of the crude oil consists in the separation of the latter into two portions, possessing distinct characteristics, called "primary oil" and "secondary oil." The average yield of the primary oil is about 35 per cent. The division is effected by mixing any quantity of the crude oil with commercial benzene, previously obtained from petroleum by distillation, using enough benzene to effect a complete separation. The mixture is placed in an open vessel, and the latter placed in a larger vessel. The benzene volatilizes and leaves the mixture, carrying with it the primary oil which drops into the larger outer vessel, the benzene itself passing off as vapour. After the benzene has all evaporated, it will be found that the crude petroleum has been divided, the inner vessel containing the secondary oil, and the outer vessel the primary oil. If the latter is to be employed as an illuminant no further treatment is necessary, but if it is to be used as a lubricant it is mixed with about one per cent. of amyl alcohol, and the mixture treated with ethyl alcohol, until it becomes milky or opalescent. The supernatant oil is drawn off, and the purified primary oil removed. The oil thus treated has a density of about 28 B. Only about one per cent. of each alcohol is usually needed to effect the removal of the small proportion of light hydrocarbons contained in the primary oil. This treatment imparts to the oil greater wearing qualities as a lubricant. The secondary oil has a density of about 36° B. It is subjected to fractional distillation as follows: The first distillate is naphtha, which is allowed to run until the temperature rises to about 120°. The receiver is then changed, and the distillation continued until the temperature reaches 288°. This second distillate is kerosene or burning oil. The receiver is changed again and the temperature raised to about 326°. This third distillate is a heavy burning oil, which the inventor calls "petrosperm" oil. The residuum left in the still is a heavy oil, which makes a good lubricant. 100 parts of crude petroleum yield 35 parts primary oil (31° B.), 3 parts naphtha (65 B.), 40 parts kerosene (50° B.), 6 parts petrosperm (36 B.), and 16 parts residuum (27 B.). No tar or waste products are obtained by this process. The purification of the kerosene is effected by adding to 95 parts of the latter 5 parts of sulphuric acid. The resulting "sludge" is allowed to subside; it is then drawn off, and the oil agitated with a small quantity of alcohol, which mixes or combines with the small portion of acid remaining in combination with the oil, and carries it to the bottom. The kerosene will now be clear, limpid, entirely free from fluorescence, neutral to test, and capable of enduring a flashing point of 54.4°. The petrosperm oil may be purified in the same manner as the kerosene, and will stand a fire-test of 149°. It contains no paraffin, and does not form a crust on the wick when burned. It is like the kerosene, almost odourless. By first separating from the crude petroleum the "primary oil," the inventor claims the removal of the principal difficulties incident to petroleum distillation by the known methods, making this portion a most valuable illuminant and lubricant. The "secondary oil," on the other hand, becomes nearly as valuable as the entire quantity of crude petroleum, from which it is obtained, would ordinarily be owing to the improvement in the products obtained therefrom, their quantity, the ease with which it can be fractionally distilled, and the absence of waste products.—D. B.

## IV.—COLOURING MATTERS AND DYES.

*Process for the Manufacture of Naphthol Sulphonic Acids.* Dingl. Polyt. Journ. 253 [13], p. 535. Brönnert and Co., Frankfurt-on-the-Maine.

IN the preparation of  $\beta$ -naphthol, a  $\beta$ -dinaphthyl ether,  $C_{20}H_{14}O$ , is formed as a by-product, which, by treating with strong sulphuric acid at a high temperature, can be converted into a sulphonic acid of  $\beta$  naphthol, thus :

To prepare  $\beta$ -naphthol disulphonic acid, 1 part  $\beta$ -dinaphthyl ether is warmed with 3 parts sulphuric acid, containing 10% anhydride, for 5 to 6 hours, at 110 to 120°C. The trisulphonic acid is obtained by heating 1 part  $\beta$ -dinaphthyl ether with 3 parts sulphuric acid, containing 10% anhydride, for 5 to 6 hours, at 110° to 120°C., adding 2 parts fuming sulphuric acid, containing 45% anhydride, and heating to 140° to 150°C. for 3 or 4 hours more.—S. H.

*Preparation of Brominized Azo-Colouring Matters.* Dingl. Polyt. Journ. 252 [6].

ACCORDING to the specification of the Société Anonyme des Matières Colorantes de St. Denis (Ger. Pat. Kl. 22, No. 26,642, December 14, 1882), all the colouring matters produced by the action of diazo compounds on phenols and amines or their sulphonic acids, are readily brominized, e.g., 100 kilos, of the colouring matter produced by the action of para-diazophenyl sulphonic acid on  $\beta$ -naphthol in alkaline solution, are dissolved in 650 litres of water, and a solution of 62 kilos. sodium bromide, and 19 kilos. sodium bromate in 500 litres of water, is added. The whole is then acidified with 130 kilos. sulphuric acid, and at the end of the reaction, neutralized with a suitable base, such as potash, soda or lime, and the colouring matter is precipitated by common salt. The whole reaction occurs according to the equation—

*On Azoresorcinol and Azoresorufinol.* Heinrich Brunner and Charles Krämer. Berl. Ber. 17, 1847.

THE authors find that the same colouring matter, Weselsky's diazoresorufinol, is produced by acting on resorcinol with Liebermann's reagent (a solution of nitrous anhydride in sulphuric acid), with Weselsky's reagent (a solution of nitrous anhydride in nitric acid, employing a dilute ethereal solution of resorcinol), and with nitrobenzene and sulphuric acid, but that other colouring matters are formed when different phenols are treated with the same reagent. The authors' results confirm those of Liebermann, but differ in some cases from Weselsky's, and they propose to name Weselsky's diazoresorcinol and diazoresorufinol, azoresorcinol and azoresorufinol respectively.

*Azoresorcinol*  $C_{12}H_8NO_4$ . The substance was prepared according to Weselsky's directions by treating a solution of 4grm. resorcinol in 300c.c. of ether with 40 to 50 drops of nitric acid, saturated at 0°C. with nitrous anhydride. The azoresorcinol formed, after recrystallization from glacial acetic acid, small lustrous cantharides green coloured crystals, which gave with alkalis a blue-violet solution with brown fluorescence. The crystals are insoluble in water and ether, and but slightly soluble in alcohol. Eight analyses gave the formula  $C_{12}H_8NO_4$ , and not  $C_{12}H_{12}N_2O_4$  or  $C_{12}H_{10}N_2O_4$  as proposed by Weselsky. The authors maintain that the reaction takes place in two stages ; the resorcinol is first converted by the nitrous anhydride into nitrosoresorcinol, and the oxygen of the nitroso group then combines with the two hydrogen atoms of the hydroxyl groups of another molecule of resorcinol forming water and azoresorcinol, thus :

*Azoresorufinol*  $C_{20}H_{14}N_2O_4$ . Prepared (a) by Weselsky's method by heating one part of azoresorcinol with 25 parts of concentrated sulphuric acid to 210°, and pouring the violet solution into water. (b) By Liebermann's method, by dissolving 5grms. of resorcinol in 15c.c. of concentrated sulphuric acid, and adding gradually 40grms. of the reagent. The mixture was heated to 140°, and poured into cold water. (c) According to Bindscheller and Busch, by warming nitrosoresorcinol with resorcinol and concentrated sulphuric acid. (d) By Brönnert's method, by heating 5grms. resorcinol, 2.5grms. nitrobenzene and 75grms. sulphuric acid to 170°. The yield by this process was, however, extremely small, para-amido-phenol-sulphonic acid being formed in larger quantity. Azoresorufinol prepared by any of these methods forms a red-brown powder, insoluble in water and ether, and difficultly soluble in alcohol. It dissolves in concentrated sulphuric acid, forming a blue-violet solution of the sulphonic acid, which is decomposed by water. With alkalis it forms a carmine-red solution with a cinnabar coloured fluorescence, the intensity of which is so great that azoresorufinol appears to be the most delicate indicator for alkalis. The composition was proved by 12 analyses. In the formation of the substance two molecules of azoresorcinol lose one molecule of water, giving an anhydride thus :

Weselsky on the other hand gives the following equation :

When nitrobenzene and resorcinol are treated with a small quantity of sulphuric acid azoresorufinol is not formed, but a mixture of compounds with green and blue fluorescence, identical with the ethereal condensation products of resorcinol discovered by Barth and Weidel (Berl. Ber. 10, 1469). Pure nitroethane gives no colouring matter with resorcinol and sulphuric acid. Di- and tri-nitrohydrocarbons and di- and tri-nitrophenol do not give colouring matters with resorcinol and other phenols, but only the mononitro compounds. This affords a further confirmation of the formulae and method of formation of these colouring matters.

*Action of Acetyl Chloride on Azoresorcinol.* Weselsky obtained a compound to which he gave the formula  $C_{12}H_8N_2Cl_2O_4$ , describing it as hexacetyl-azoresorufinol in which each nitrogen atom is combined with two chlorine atoms. The authors obtained the substance in the form of gold-yellow lustrous scales, soluble in sulphuric acid and alkalis, forming a blue solution, which became violet on warming. The formula was found to be  $C_{12}H_8Cl_2NO_4$ , and the authors describe the compound as the hydrochloride of the body  $C_{12}H_8ClNO_4$ , and give it the constitution  $C_6H_3(OH)(CH)NCl(O_2)C_6H_4$ . Its formation takes place thus—

Azoresorcinol and Azoresorufinol combine, not only with bases, but also with acids to form salts, and therefore the nitrogen must be trivalent in these compounds. Only one molecule of hydrochloric acid combines with each atom of nitrogen, and the chlorine precipitates silver from silver nitrate. The mother liquor from the yellow crystals yielded, on evaporation and treatment with alcohol, an amorphous greenish lustrous substance, a derivative of azoresorufinol, which formed with alkalis a red solution with cinnabar coloured fluorescence. Its composition was found on analysis to be  $C_{20}H_{14}N_2Cl_2O_4$  or  $C_{20}H_{14}Cl_2N_2O_4$ , and the authors give it the constitution—

By heating with acetic anhydride and anhydrous sodium acetate diacetyl-azoresorufinol was obtained. Its composition  $C_{20}H_{14}(C_2H_3O)_2N_2O_2$  or

was proved by analysis. By heating with alkalis azoresorufinol was reformed. Azoresorufinol hydrochloride,  $C_{12}H_{12}Cl_2N_2O_2 \cdot 2HCl$ , was prepared by heating azoresorufinol with fuming hydrochloric acid to 100°, thus— $2(C_{12}H_{12}NO_2) + 4HCl = C_{12}H_{12}Cl_2N_2O_2 \cdot 2HCl + H_2O$ .

*Hydrochloride of hydro-azoresorufinol ether.* Azoresorufinol and azoresorufinol give the same reduction product with nascent hydrogen both in acid and alkaline solution. By warming azoresorufinol with tin and concentrated hydrochloric acid the compound described by Weselsky as hydro-diazo-resorufinol is formed. It occurs in colourless scales like mother of pearl, which, on standing in the air, assume the colour and coppery lustre of sublimed indigo, and which, on oxidation, are easily converted into azoresorufinol. The formation of the substance resembling indigo depends on the loss by the crystals of hydrochloric acid and water of crystallization. The latter could not be determined directly for the substance decomposes at 100°. The composition of the compound was found on analysis to be  $C_{12}H_{12}N_2O_2 \cdot 4HCl + 4H_2O$ . When dried quickly on the water bath the crystals yield a blue powder, from which crystals, resembling potassium permanganate, may be obtained. When crystallized from alcohol the composition was found to be  $C_{12}H_{12}N_2O_2 \cdot 3HCl$ , and from acetone  $C_{12}H_{12}N_2O_2 \cdot HCl$ . The formation of the compound is thus described: Azoresorufinol loses water and forms azoresorufinol; the same process is repeated, two molecules of azoresorufinol losing one molecule of water, and forming an ether thus—

And this ether takes up 16 atoms of hydrogen. The formation of Barth and Weidel's di- and tetraazoresorufinol ethers is analogous to the above. In the reduction process probably each benzene group takes up two atoms of hydrogen, and the nitrogen combines with hydrochloric acid. Dilute alkalis in presence of air convert the substance first into azoresorufinol, and finally into azoresorufinol.

*Tetrahydroazoresorufinol.*  $C_{12}H_{16}N_2O_2 \cdot H_4$ . This compound is prepared by the action of zinc and concentrated hydrochloric acid on azoresorufinol in the form of dark blue crystals with coppery lustre. At 100° it is converted into azoresorufinol. The hydrochloride  $C_{12}H_{16}N_2O_2 \cdot 2HCl$  was analysed. The same compound is formed by the action of hydrogen sulphide on an ammoniacal solution of azoresorufinol. With sodium amalgam azoresorufinol yields a very unstable leuco-compound, which is colourless, but rapidly assumes an indigo-blue colour in contact with the air.

*Dibromo-azoresorufinol hydrobromide,*

was prepared by dissolving azoresorufinol in caustic soda, and saturating the solution with bromine in the cold. A brown precipitate was produced, which on recrystallization from alcohol, yielded a cantharides-green lustrous mass. The substance was analysed.

*Hexa-bromo-azoresorufinol hydrobromide,*

This compound was prepared like the one last described, from azoresorufinol, but the mixture was warmed. It forms a red amorphous mass, which gives with alcohol a violet solution with blood-red fluorescence. The composition was proved by analysis.

*Tri-nitroazoresorufinol.*  $C_{12}H_6(NO_2)_3NO_2$ . According to Weselsky azoresorufinol and azoresorufinol yield tetraazoresorufinol with concentrated nitric acid, but his results were not confirmed by those of the authors. The action of nitric acid is very violent, and great care must be

taken to prevent loss. Weselsky's tetraazoresorufinol nitrate—

is described by the authors as tri-nitroazoresorufinol,  $C_{12}H_6(NO_2)_3NO_2$ , and his tetraazoresorufinol nitrate,  $C_{12}H_6N_6O_{12} \cdot 6NO_2 = 11H_2O$ , as hexa-nitroazoresorufinol,  $C_{12}H_2N_6(NO_2)_6$ . The first compound was obtained in the form of small lustrous cantharides-green crystals. The alcoholic solution has an indigo-blue colour. The second compound was prepared from azoresorufinol, and formed fine cantharides-green needles, dissolving in water, alcohol and ether, with a purple colour. A complete analysis of the first compound was made, and the nitrogen in the second determined. By the action of tin and hydrochloric acid on the nitro-compounds the authors obtained amidoazoresorufinol, amidoazoresorufinol, and amido-derivatives of the hydroazoresorufinol ethers.—S.Y.

*On the Amidophenol Sulphonic Acids and their Relation to Liebermann's Colouring Matters.* Heinrich Brunner and Charles Kramer. *Berl. Ber.* 17, 1867.

When nitrobenzene and resorcinol are heated with concentrated sulphuric acid to 160–170°, azoresorufinol and para-amidophenol-sulphonic acid are formed. The mixed precipitate was dissolved in warm ammonia, and precipitated while hot with hydrochloric acid. The azoresorufinol separated at once, and the acid crystallized from the filtrate after cooling in white lustrous needles. After recrystallization from hot water they were analysed, and the composition was found to be

The solution of the crystals in water or alcohol reduces an ammoniacal solution of silver nitrate in the cold, and gives a violet colour with ferric chloride. The crystals become brown in contact with the air.

Nitrobenzene alone does not give the acid when heated with concentrated or fuming sulphuric acid, hence the azoresorufinol must be concerned in its formation. In the production of Liebermann's colouring matters from nitrosophenols, the oxygen of a nitroso-group appears to combine with two hydrogen atoms of the hydroxyl groups of one polyvalent or two mono- or polyvalent phenol molecules to form water, so that the colouring matters contain the groups

Since azoresorufinol is formed from nitrosoresorufinol and resorcinol, thus:—

When nitrobenzene and resorcinol are heated with concentrated sulphuric acid, a transposition of atoms must occur, the nitrobenzene yielding para-nitrosophenol and the divalent radical  $\begin{array}{c} HO \\ | \end{array} C_6H_3N =$ , thus:—

Sulphur dioxide is evolved, and thus nascent hydrogen may be produced. The oxygen of a nitroso group unites with the hydrogen of resorcinol to form water, the resulting group  $\begin{array}{c} HO \\ | \end{array} C_6H_3N =$  combining with hydrogen to form para-amidophenol, while the divalent radical  $\begin{array}{c} HO \\ | \end{array} C_6H_3N =$  combines with the group  $\begin{array}{c} O \\ | \end{array} C_6H_4$  formed from resorcinol, and yields azoresorufinol: thus:—

The sulphuric acid then forms the sulphonic acid of para-amidophenol and converts azoresorcinol into azoresorufol.

The action of the homologues of nitrobenzene and of the three isomeric nitrophenols on resorcinol and sulphuric acid was studied.

Paranitrotoluene and resorcinol yielded a dimethyl ether of azoresorufinol, and para-amidophenol-sulphonic acid. The conversion of the ethyl groups of the benzene ring into methoxyl groups in the formation of azoresorufindimethyl ether is surprising, the more so as in the amidophenol sulphonic acid the ethyl group is liberated. In the formation, however, of the amidophenol sulphonic acid from nitrobenzene or nitrotoluene, an oxygen atom is transferred from the nitro group to the carbon atom in the para-position, and the authors consider it certain that a dimethyl ether, and not an isomeric dimethylazoresorufinol is formed.

Neither ortho- nor meta- but only paranitrophenol give with resorcinol colouring matters resembling azoresorufinol, while para-amidophenol sulphonic acid is formed as a by-product in each case. Hydroquinone and pyrocatechol do not give colouring matters either with nitrobenzene or nitrous acid, but they do yield amidophenol-sulphonic acids.

From the authors' researches it appears also that only mono- and not dinitrosophenols yield colouring matters. Thus mononitrosoresorcinol and mononitroso-oreinol give colouring matters with resorcinol and oreinol, while Fritz's dinitrosoresorcinol (Berl. Ber. 8, 631) and Stenhouse's dinitroso-oreinol (Annalen 188, 353) give no colouring matters with resorcinol and oreinol. These facts afford a further proof that the phenol colouring matters contain the trivalent group  $-N=O=$ , combined with two or three benzene rings, and not two atoms of nitrogen to 12 or 18 atoms of carbon.

*Para-amidophenol sulphonic acid and phenol colouring matters.*—When the acid is heated, a small quantity of a dark violet sublimate is formed. In its properties it cannot be distinguished from Liebermann's phenol colouring matter  $C_{12}H_5NO_6$ . Its formation may be explained thus:—

The ortho- and meta-amido phenol sulphonic acids when subjected to dry distillation yielded no trace of colouring matter.

(a) *Amidoresorcinol-sulphonic acid and azoresorcinol.*—The yellow non-volatile nitrosoresorcinol, melting at  $115^\circ$ , which, according to Weselsky and Benedikt, has the constitution 1:3:4, was converted into the corresponding amidosulphonic acid. Green glittering scales were obtained, but Hazura describes the acid as occurring in reddish prismatic crystals. When heated in a glass tube a dark violet sublimate of either azoresorcinol or azoresorufinol was obtained, according to the temperature, thus:—

(v) *Amidoresorcinol-sulphonic acid.*—The red volatile nitrosorcinol to which Weselsky and Benedikt give the constitution 1:2:3 was converted into the amidosulphonic acid which crystallized in colourless prisms. On heating this acid no colouring matter was obtained.

The authors draw the following conclusions from their results with regard to Liebermann's colouring matters. Since (1) only paranitrophenol, para-amidophenol sulphonic acid, and para-amidoresorcinol sulphonic acid (also paranitrotoluene) and not the corresponding ortho- and meta-compounds yield colouring matters; (2) of the diatomic phenols only resorcinol and neither hydroquinone nor pyrocatechol yield colouring matters; (3) nitrosoresorcinol and nitroso-oreinol yield colouring matters when heated with resorcinol or oreinol and concentrated sulphuric acid, but not when heated with hydroquinone or pyrocatechol; it follows that in Liebermann's colouring matters the nitrogen atom occupies the para position with regard to a hydroxyl group, and that of the poly-

atomic phenols only those in which the hydroxyl are in the meta position can form the colouring matters. The following characteristic groups are therefore present in these substances:—

—S. Y.

*Improvements in the Manufacture or Production of Colouring Matters from the Tetrazo-compound of Benzidine Disulphonic Acid.* John Peter Griess, Barton-on-Trent. Eng. Pat. 1074, January 9, 1884.

THE disulphonic acid mentioned (which is the disulphonic acid of diamido-diphenyl) is diazotised and combined with the naphthylamines and methylphenyl, or naphthyl naphthylamines, and their sulphonic acids. As an example is given the action of the tetrazo compound upon naphthionic ( $\alpha$ -naphthylamine-sulphonic) acid, which takes place in neutral or alkaline solution with the production of a red dye stuff which has the property of dyeing cotton goods without the use of a mordant.—R. M.

*Improvements in the Manufacture or Production of Colouring Matters obtained from Sulpho-derivatives of Benzidine, and in the Preparation of such Sulpho-derivatives.* John Peter Griess, Barton-on-Trent. Eng. Pat. 1099, January 9, 1884.

FOUR new sulphonic acids of benzidine are described:—

All of these acids are produced by heating sulphate of benzidine with three to four parts of fuming sulphuric acid to  $170^\circ$  to  $200^\circ$  C. for one hour, taking care that charring does not take place. The mixed acids can be separated from one another by fractional extraction with water, or by converting them into calcium or barium salts and crystallizing; but in practice the mixture of acids can be made use of, although the author finds it preferable to convert the sulphonic monosulphonic into the corresponding disulphonic acid, owing to the superiority of the dyes from the latter. The remainder of the process is similar to that described in the foregoing specification, the benzidine sulphonic acids being diazotised and combined with amines and phenols, and their sulphonic acids. A typical illustration of the process is given for producing a dark cotton-red from tetrazo-benzidine trisulphonic acid and  $\beta$ -naphthol in alkaline solution.—R. M.

*Improvements in the Manufacture of several Monosulphonic Acids of  $\beta$ -Naphthylamine.* Emil Elsässer, Barmen. Eng. Pat. 7712, May 14, 1884.

$\beta$ -NAPHTHYLAMINE is dissolved in three times its weight of fuming sulphuric acid, containing 15 to 20 per cent. of anhydride, and heated to  $70^\circ$  to  $75^\circ$  C., till a sample remains clear on dilution and the addition of ammonia. The melt is diluted with five times its weight of cold water and filtered to remove the more difficultly soluble monosulphonic acids, after being pressed, are converted into sodium salts. This insoluble acid is stated to consist of three modifications, which are separated in the following way:—The dried sodium salt is digested for an hour with 93 to 96 per cent. alcohol, and filtered. The residue consists of the sodium salt of

the monosulpho acid No. I., and the filtrate containing the other two modifications is evaporated, dissolved in water, and the sulpho acid precipitated by hydrochloric acid, and then converted into Ca or Ba salts. The solution of these salts is allowed to crystallize when the salt of acid No. II. first separates out in small quantity and the solution contains the new acid No. III., which, in the free state, is very difficultly soluble in water. Other methods of producing and separating these isomeric acids are described.—R. M.

*Improvements in the Manufacture of Red Azo Dye Stuffs or Colouring Matters.* Emil Elsasser, Baumen. Eng. Pat. 7713, May 14th, 1884.

This invention relates to the preparation of azo colours from the new  $\beta$ -naphthylamine monosulphonic acid No. III., or from mixtures of the acids II. and III., described in the previous specification. The acids are diazotised in the usual way, and combined with "the  $\alpha$ -naphthol sulpho acids obtained from Piria's naphthionic acid and Laurent's sulpho-naphthalidamic acid (i.e., the  $\alpha$ -naphthol monosulphonic acids may be obtained from naphthionic acid or sulpho-naphthalidamic acid)."—R. M.

## V.—TEXTILES: COTTON, WOOL, SILK, &c.

*A New or Improved Process of Scouring and Washing Wool and other Materials, and Apparatus for the Purpose.* Ernest de Pass, London. Eng. Pat. 973, January 8, 1884.

This patent refers to a process of thoroughly scouring and washing wool and certain other raw material. It entails the use (1) of a solvent of fatty bodies, other than sulphuret of carbon, preferably toluene, (2) of water as a solvent of substances other than fatty bodies. The operations are principally carried on in a rarified medium, and a full description (with plates) is given of the requisite plant.—A. J. K.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*Diehl's Apparatus for Neutralising and Fixing Colours in Cotton Goods by Ammonia Gas.* Dingler [522], Heft 6, pp. 256 to 258.

THE idea of neutralising and fixing by ammonia gas is an old one. During a number of years apparatus for this purpose have found their way into use, especially

slow evaporation of acetic acid, the idea is to precipitate it by a direct chemical neutralisation.

O. Diehl (Ger. Pat., Kl. 8, No. 21077, March 14, 1882), has specified an ammonia apparatus. The goods on which the printed colours are to be neutralised or fixed, are wound on to rollers II., which can be set into slow motion from the outside. The apparatus is then closed tight. By lifting the safety valve *e*, ammonia solution is poured through the tube *a*, into the small double-bottomed evaporation pan *b*, and evaporated by means of steam through the tube *c*. The apparatus is at the same time warmed by the worm *d*, whereby the condensation of water during the work is prevented. The plate *e* is placed to receive any water condensed on the roof, and prevent it injuring the goods. At the end of the reaction, in order to remove the last traces of ammonia, steam is blown in at the pipe *g*, leaving by the cock *j*.—F. L. T.

*An Improved Process for Colouring Paper in Endless Rolls, and in Apparatus to be Employed Therewith.* W. H. Beck, London. Eng. Pat. 12372, Sept. 13, 1884.

THE above title contains all the information that can profitably be abstracted from this specification, which is accompanied with drawings.—A. J. K.

*Improvements in the Printing of Indigo upon Textile Fabrics.* G. H. Underwood, Manchester. Eng. Pat. 421, January 2, 1884.

THE surface of the textile fabric is "padded" or printed with a sulphide of arsenic, either thickened with starch or in solution of an alkali or alkaline carbonate. The cloth thus mordanted is now printed with the following preparation of indigo:—Commercial indigo is ground with water or alkali to the consistency of a thick paste; to this is added thickening material, such as British Gum or starch, and to the whole, when thoroughly stirred, is further added a strong solution of caustic soda, which is also thoroughly mixed in with the other ingredients to form a uniform paste, which is used for printing. By subjecting the cloth thus prepared and printed to the action of steam, the indigo becomes de-oxidised to indigo-white. In the subsequent processes of ageing, scouring, and washing the indigo re-absorbs oxygen, and is finally printed blue upon the cloth.—A. J. K.

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

*Improvements in the Manufacture of Glass.* Dingl. Polyt. Journ. 253 (13), p. 529.

FOR the manufacture of a marble or jasper-like glass (Weiskopp & Co., Morchenstern in Bohemia, Ger. Pat. 27087, 1883, fuse 100 parts sand with 3 parts sodium sulphate, 4 parts iron peroxide, 12 parts plumbago or charcoal, 36 parts sodium carbonate, 12 parts lime, and 12 parts potassium carbonate. In order to decorate the glass, 1 part silver sulphide and 5 parts iron peroxide are employed, whereby especially dark green lines come into prominence. One part silver sulphide and from 5 to 10 parts manganese peroxide produce dark brown lines.

The invention of M. N. Schmitt, Ringen (Ger. Pat. 26161, 1883), relates to producing a permanent silver polish on bottles for wine, liquor, etc. Aluminium is dissolved in concentrated hydrochloric acid, and a coating of that solution applied on the bottles. They are then heated, whereby they assume a silvery appearance. According to another process, fine washed pure alumina, in the form of a paste, is laid on the bottles. They are then heated, and carbon bisulphide is made to pass over them so long until all alumina is converted into aluminium sulphide (?), when a silvery surface will make its appearance.

A. Schierholz, Plauen (Ger. Pat. 26080, 1883), decorates glass by applying a coating of syrupy enamel on a certain spot, then covers it with small beads and burns

for the fixing of mordants. Instead of allowing the metallic hydrate or basic salt to fix itself to the fibre by

them in the glass. In the same manner so-called cathedral glass can be made.

W. B. Fitch, Deptford (Ger. Pat. 26693, 1883), recommends for decorating glass goods with enamel, passing them before cooling down in the cooling furnace across a revolving asbestos-roller, which is covered with a hot enamel mass. On certain raised spots the enamel is taken up, which hardens and adheres firmly to the glass after passing through the cooling furnace.—S. H.

### X.—METALLURGY, MINING, ETC.

*Recent Improvements in Metallurgical Operations.* Dingl. Pol. Journ. 253 (12), p. 305-309.

G. v. GIESCHE, Breslau (Ger. Pat. 25069, 1883), roasts blende by heating it at first moderately in a couple of burners *n* (fig. 1 and 2) which are supplied with air by a

into the bottom kiln *c* to be roasted at a high temperature. The burners *n* are then again charged with fresh ore through the doors *a*.

J. v. MISKEY (Oesterr. Zeitschr. für Berg- und Hüttenwesen 1883, 521) proposes to employ a regenerative furnace for lead-smelting. If the slides *F* and *f* have the position as represented in fig. 3, 4 and 5, air is drawn into the regenerators *h* through the open channel *k* owing to the aspirating action of the chimney, connected with the flue *g*. Having taken up heat on its course through the channels *h* on the left side, the air passes over the bridge *o* and the hearth *a*, where it gives off a considerable portion of its heat and proceeds over the opposite bridge into the chamber *b* to mix here with producer gas, coming from *c*. The heat of the combustion taking place here is employed to heat the channels *h* on the right side, through which the gases escape on their way to the chimney. By moving the slides *F* and *f* the direction of the gases can

fig. 1.

fig. 2.

fig. 3.

fig. 4.

Körting's injector. Slides *s* separate these burners from the kiln *c* which is worked with hot air. The gases generated here are rich in sulphurous acid compared with those produced in the top kilns. All gases, however, meet in the main flue *h* and the mixture is said to be rich enough for making oil of vitriol with advantage. When the roasting of the blende in *c* is complete, it is discharged and, by withdrawal of the slide *s*, the charge in *n* falls

be reversed. For the manufacture of metallic lead a layer of liquid lead, 10 to 15 cm. high, is first made on the hearth *a* and galena is afterwards introduced. The impurities collecting on the surface are removed with a scoop. By opening the tap *u* air is pressed through the small openings *s* at the bottom of the hearth into the molten lead, which is hereby oxidised. The oxide of lead mixes intimately with the galena and at the end of the

operation metallic lead can be drawn off by the tap *te*.

whence it gradually sinks down into the shaft *d*. Producer gas enters the furnace at the bottom and after passing through the red hot layer of ore escapes along

patented a shaft furnace for making both zinc and lead from plumbiferous zinc ores. The mixture of ore and coal is charged into the iron hopper *a* (figs. 6, 7, 8 and 9)

with the metal vapours through a series of fireclay receivers and iron condensators, which condense the zinc, into the chimney. The charge deprived of its zinc gra-

dually reaches the working doors and is withdrawn at regular intervals. The object of this mode of working is to avoid the admission of air in excess, which would act oxidising on the zinc vapours in the top part of the furnace. Along with the producer gas just sufficient air is introduced into the furnace to produce the combustion of the gases. The reduced lead drops on a fireclay hearth at  $r_1$ , thence in a gutter, and is collected in boxes placed below.

L. Kleemann, Mislowitz (Ger. Pat. 26789, 1883) describes a condensation arrangement for zinc furnaces. The flue K (figs. 10, 11 and 12) is in connection with chambers B, whose upper part is filled up with parallel rows of shutter-like plates turning round a central pivot. Iron bars  $c$  and levers  $e$  are fastened in a manner, that one guide-rod  $d$  is sufficient to work two sets of shutters.

fig 14.

The gases of the process try to pass between the spaces and since they find many obstacles in their way they have to unroll themselves, as it were, depositing any solid matter which they carry with them. The increased surface, thus offered and the oblique position of the shutters is also favourable for condensation. As soon as the plates are filled up with dust, a to and fro movement of the rods  $d$  causes the solid matter to scale off and fall down to the bottom.

The Ems Lead and Silver Works (Ger. Pat. 26006, 1883.) places baffle-plates in flues in order to catch any solid matter mechanically carried away by gases. These plates have an oblique position and this is attained by fastening them to a bar  $b$  outside their centre of gravity (fig. 13), or by suspending them from the top with hooks

fig 15

of a special shape (fig. 14), or better still by fastening them to a bar  $b$  and allowing them to rest on a rod  $s$  provided with barb-bolts (fig. 15). If the rod  $s$  has a handle outside the flue, the latter arrangement allows of altering the position of the plates at will, which will be found very convenient for cleaning.

#### Notes on the Siemens-Martin Steel Process. Dingl. Polyt. Journ. 253 (12 and 13) p. 509-514.

AL. JUNGCK has published an investigation on the practical details of the Siemens-Martin process as carried out at the "Phoenix" works of Ruhrort. The gas-producer consists of eight chambers, which are charged every three hours with 600kg. coal of the following composition:—

C	71.10
H	1.21
O & N	11.32
Ash	12.71

The gas of two chambers suffices for one furnace, each of which is provided with four regenerative chambers. The author reports on two operations, a normal and an irregular one. In the first instance the furnace was charged at 3 a.m. with:—

300kg. Bessemer pig-iron.
100 Maryport, and
150 Spiegel.

After 45 minutes the mass was in a fused state, and about every 45 minutes the following additions were made:—

2 charges each of 350kg. Bessemer rail ends.
1 .. .. 300 Bessemer steel.
3 .. .. 300 Bessemer rail ends.
1 .. .. 300 Bessemer steel.
2 .. .. 250 Bessemer rail ends.

At 11.40 a.m. 115 kg. Spiegel were added, when the steel possessed the hardness required (just 5 of the Styrian scale) and was tapped. Previous to every addition a sample was drawn and examined for the nature of the fracture. The first sample was fibrous on the edge, fine-grained, and light-grey in the inside, and of a smooth surface. After the first addition of Bessemer rail, the fracture was less fibrous and quite white, the graphite having been converted into chemically-combined carbon. Gradually the fibrous structure disappeared altogether, and the grain of the fracture slowly passed from fine-grained pig-iron to fine-grained steel. After the 7th charge, the sample had the appearance of a good fine-grained, but rather hard steel. One would feel inclined to interrupt the process at that stage, to save the addition of ferro-manganese or Spiegel at the end, but this would not be economical, since the quantity of steel ends worked up is larger by one-third for an equal amount of pig-iron and Spiegel. Besides, the result would be too uncertain. From the 8th charge the formation of ingot-iron sets in. The fracture becomes coarse-grained, and the sample is completely permeated by blisters of a longish shape. But when the steel is finished, its surface is again smooth and little blistered, showing that all gas-bubbles have escaped. The product had all the physical proportions of a good Martin-steel, and tested on analysing:—

Mn	0.304
C	0.336
Si	0.035
P	0.160
S	0.006
Fe (with a trace of Cu)	99.159

The small percentage of silicon is remarkable, and indeed distinguishes Martin-steel from all other kinds. Whereas there was 17.7kg. Si in the charge, the steel run off only contained 1.38kg. Si, showing that 12-13ths of the total silicon went into the slag. In the same manner, of 38.9kg. C, which were put into the furnace, 13.3kg. C remained in the steel while 25.6kg. C were oxidized. The slag tested as follows:—

SiO <sub>2</sub>	50.18
P <sub>2</sub> O <sub>5</sub>	0.29
S	6.01
FeO	25.75
Al <sub>2</sub> O <sub>3</sub>	2.61
MnO	20.41
CaO	0.62
MgO	0.17

99.501

It is also worth mentioning that on cooling, the slag rises considerably, giving off large volumes of carbonic oxide, which burns with a blue flame. The liquid slag, therefore, absorbs carbonic oxide in large quantities.

In a second operation the furnace was worked too cold, although plenty of gas was burned. The batch was started at 7.0 a.m., with:—

350kg. Ruhrort grey Bessemer pig-iron.
150 Spiegel, and
100 English pig-iron.

After fusing, the following additions were made, every 15 to 10 minutes up to 2.10 p.m.:—

2 charges, each of 350kg. Bessemer ends.
1 .. .. 300 Puddle-steel ends.
1 .. .. 300 Bessemer & Martin steel rail.
2 .. .. 250 .. ..

At the conclusion, 125kg. Spiegel were added, but the steel being too soft, two other charges of 40kg. and 10kg. Spiegel were made, until the steel had the hardness of 5 (Stryan scale) when it was tapped at 2.40 p.m.

An average sample of the producer-gas, employed for heating during this operation, tested:—

	Per cent. by Volume.	Per cent. by Weight.
N .....	61.49	61.83
CO <sub>2</sub> .....	1.15	7.36
CO .....	23.21	21.50
Hydrocarbons .....	2.07	1.21
H <sub>2</sub> .....	6.19	0.55
Steam .....	2.26	1.32

There were present in the gas 13.61 per cent. by weight of soot, and 0.9 per cent. tar. Since the gas only contained about 27 per cent. of combustible constituents, the decreased temperature of the furnace can be easily accounted for. The fire-gases contained 0.13 per cent. soot, whereas the tar was completely burnt. They tested:—

	Per cent. by Volume.	Per cent. by Weight.
N .....	68.17	63.71
CO <sub>2</sub> .....	12.76	19.23
CO .....	1.73	1.66
H <sub>2</sub> .....	0.78	0.05
O .....	6.05	6.46
Steam .....	10.51	6.57

In considering the different methods of steel-making, the author compares the Siemens-Martin process with a much-protracted puddling operation. The former, however, is carried out at a great deal higher temperature and with a mass, always in a fused state.—S. H.

*Analysis of some old Indian Bronze and the Patina of the Same.* By A. Arche and C. Hassack. Dingl. Polyt. Journ. 253, (13) p. 514 to 519.

THE specimens were taken from two old Indian kettledrums, one of which was patched with a third bronze. The quantitative analysis was performed as follows: The alloys were dissolved in hydrochloric acid, adding gradually some nitric acid, filtering and precipitating with sulphuretted hydrogen. In the filtrate from this iron was separated by ammonium sulphide, and lime by means of ammonium oxalate. The precipitate with sulphuretted hydrogen was digested with sodium sulphide to extract tin, antimony and arsenic, which were separated according to H. Rose's method. The precipitate insoluble in sodium sulphide was dissolved in nitric acid, treated with sulphuric acid for precipitating lead and then with sulphuretted hydrogen to estimate copper as cuprous sulphide. Another portion of the alloy was oxidised with hydrochloric and red nitric acid, to determine sulphur as sulphuric acid. The insoluble residue was considered as SiO<sub>2</sub>. An elementary analysis yielded the carbon, whereas the water found was calculated as constitutional water. In order to get at the oxygen contained in the oxides a reduction in a current of hydrogen was performed and after deducting the water found in the elementary analysis, the rest was calculated as oxygen. The following figures were thus obtained:—

	A.	B.	Stuff for patching.
Cu .....	60.82	70.79	68.78
Pb .....	15.68	11.25	17.55
Sn .....	10.88	1.90	6.88
Sb .....	1.16	3.21	—
As .....	trace	0.79	—
Fe .....	0.91	0.30	0.85
CaO .....	0.38	0.12	trace
SiO <sub>2</sub> .....	1.13	1.26	0.29
S .....	1.37	2.20	1.49
C .....	1.05	0.94	0.70
H <sub>2</sub> O .....	2.92	0.89	1.89
O .....	3.13	—	0.66
	99.43	99.65	99.09

By leaving out those figures which are unimportant for the composition of bronze, the figures can be better compared with each other. The patch of the drum B was fastened with iron rivets, the iron of which tested:—

Fe .....	97.43
C .....	2.20
S and P .....	traces
	99.63

There was also some solder, testing thus:—

Cu .....	66.70
Pb .....	3.78
Sn .....	0.55
Zn .....	23.97
Fe .....	0.82
SiO <sub>2</sub> .....	0.12
As, S, Co, Ni .....	traces
H <sub>2</sub> O, CO <sub>2</sub> loss .....	4.06
	100.00

Or if the sum of the essential components be equal to 100, there is:—

Cu .....	69.62
Pb .....	3.91
Sn .....	0.57
Zn .....	23.02
Fe .....	0.85
	100.00

The surface of the bronze was covered with a layer of oxidised metal Patina—of beautifully green colour which was subjected to the following method of analysis. The loss of weight by drying in the desiccator was stated as moisture. The powder was then treated with dilute hydrochloric acid, evaporated to dryness, etc., to separate silica. The residue was dissolved in water and the bases separated as described above for the bronze. Carbonic acid was gravimetrically estimated and there was also made an elementary analysis of each sample. The figures were thus:—

Patina	A.	B.	Stuff for patching
Spec. grav. ....	3.192	2.585	—
Moisture .....	0.73	0.19	1.09
CaO .....	28.08	11.00	26.11
PbO .....	1.95	0.59	12.38
SnO <sub>2</sub> .....	0.15	0.05	10.52
Fe <sub>2</sub> O <sub>3</sub> + Al <sub>2</sub> O <sub>3</sub> .....	2.82	1.11	1.16
CaO .....	1.19	0.31	5.06
MgO .....	trace	trace	0.27
SiO <sub>2</sub> + Insoluble .....	15.29	77.51	15.21
SO <sub>2</sub> .....	trace	trace	0.97
CO <sub>2</sub> .....	6.33	1.60	5.11

Result of the elementary analysis:

H <sub>2</sub> O .....	7.16	4.89	12.12
CO <sub>2</sub> .....	11.26	6.34	19.26

From these figures, leaving out the unimportant constituents, the authors conclude the following chemical composition for the three Patinas:—

Patina A.		85.83
CuCO <sub>3</sub> .20H <sub>2</sub> O .....		13.01
2PbCO <sub>3</sub> .PbO <sub>2</sub> .H <sub>2</sub> .....		1.16
SnO <sub>2</sub> .H <sub>2</sub> .....		100.00
Patina B.		
CuCO <sub>3</sub> .30H <sub>2</sub> O .....	95.11	56.08
2PbCO <sub>3</sub> .PbO <sub>2</sub> .H <sub>2</sub> .....	1.19	21.62
SnO <sub>2</sub> .H <sub>2</sub> .....	0.10	19.30
	100.00	100.00

—S. H.

#### XIV.—AGRICULTURE. MANURES, Etc.

*Treatment of Bones.* Dingl. [252] Heft. 6.

F. A. RISSMÜLLER, (German Patent No. 26,697, Aug. 30, 1883.) dissolves the unbroken raw bones in warm sulphuric acid, skimming off the fat, which is remarkable for its purity. He uses leaden pans, and sulphuric acid of 45° B., warmed to 60° (140° F.). Into this warm sulphuric acid a certain amount of bones is placed; these dissolve in three days to a clear solution, the fat swimming on the top. The fat, when skimmed off, is washed free from sulphuric acid by warm water. The remaining solution is mixed with calcium phosphates, producing superphosphate, with soluble phosphoric acid, and soluble nitrogen.—F. L. T.

*On the Cultivation of the Sugar-Beet in England in 1884.*  
Abstract of a Report by Prof. A. B. Church.

[This report is based on a careful inspection of the chief districts where sugar-beets have been grown during the past year for the new sugar factory of Messrs. Bolton and partners.]

The effect of last year's drought told unfavourably, as regards regularity and yield, but still the results of this first year's experience prove encouraging. If the weight of the crops has been small in some instances, yet a yield of about 12 tons per acre has been secured on a large proportion of the farms, whilst the average quantity of sugar in the roots nearly reached 13 per cent., corresponding to a production of 1½ tons of crystallisable sugar per acre. Whilst the yield per acre in a few cases has been less than five tons, in others it has exceeded 15, or been as high as 20; and the whole 640 acres have produced a total of about 6,850 tons of roots, or over 10 tons per acre. Two conditions of successful sugar-beet growing, are, (1) *as close planting as possible*, and (2) that the roots do not average in weight more than something below 1½ lb. apiece. By observance of these rules good results, both as regards quantity and quality, are secured, other things being equal. To have *as close a plant as possible* is, indeed, termed by the author the "golden rule" for the sugar-beet grower. Small roots and many of them are best, both for the grower and the sugar maker, for the smaller the root the richer it is in sugar, the less saline matter does it extract from the land or the manure, and the easier it is to lift. Moreover, when the roots are near to each other the bulbs are not so much exposed, and the proportion of leaf to root is smaller; they are also less likely to grow *fanged and forked*. The following table shows the advantage of a close plant:—

(L)	(II)	(III)	(IV)
Distance between the drills.	" " " " the single plants in the rows.	" " " " the number of roots per acre.	" " " " the yield per acre, assuming each root to weigh 1½ lb.
(L)	(II)	(III)	(IV)
15 ins.	6400	39,696	31 tons 2 cwt.
18 "	9 "	38,720	17 " 0 "
18 "	12 "	29,040	12 " 19 "
18 "	15 "	23,232	10 " 7 "
21 "	18 "	15,000	6 " 12 "

With regard to the question of *suitability of manures*, when the improved stromia process of Messrs. Bolton and partners is used, by which the sugar is directly precipitated from the beet-juice, then superphosphate of lime, nitrate of soda, and other artificial manures, suitable for sugar-beets, may be employed, for the increase thus caused of saline matter in the roots no longer interferes with the extraction of the sugar. Farmyard manure should never be applied directly to the sugar-beet crop, but to that which precedes it. Where it has been used, especially in the spring, the roots have been uneven in size, coarse in quality, and much fanged. In light soils and dry seasons farmyard manure may help to secure a tolerable yield, but at the sacrifice of almost every desirable character in the root. Another condition of importance is *cleanness of the land, i.e.*, freedom from weeds, amongst which, especially *cock grass*, which is very prejudicial. Besides "thick sowing," it is also very important that early thinning and careful singling be observed; moreover, earthing of the exposed part of the roots; cutting off any "bolted" or runaway stems; selecting the proper time for pulling the crop; drawing without wounding the roots; with many other minor details of cultivation. Despite the scepticism amongst well informed and even scientific men, as to the production in this country of a crop of sugar-beet having a high proportion of sugar, the author adduces proof of the soundness of the position assumed by the advocates of English sugar-beet growing, in the recital of experiments made on the large scale in 1884, in Surrey, Berks, Oxfordshire, Middlesex, Northamptonshire, Lincolnshire, Staffordshire, Worcestershire, Warwickshire, Suffolk, Norfolk, Cambridgeshire and Essex, and also County Wexford, Ireland, which show perfectly encouraging results, although the year cannot be regarded as a favourable one in point of weather and other natural conditions. Though it is stated that a hot dry summer is the only one

suitable for the sugar beet growth, this statement cannot be taken without modification, and it becomes the reverse of the truth with a shallow and gravelly soil, and when the spring rains have not sufficed for the regular germination of the seed.

Touching the *best time for gathering*: in the Cirencester experiments of 1870 and 1871; during the former year the increase of sugar continued up to and even after the middle of October; during the latter it practically ceased a week earlier. In both years, during the first half of November, the amount of sugar remained practically stationary, but afterwards a decided diminution of the percentage became apparent. Although observations of rainfall and temperature during the latter part of the autumn serve in guiding to a judgment as to the probable saccharine ripeness of the crop, it is by far the best to take a fair sample of roots, and ascertain the exact content of sugar by determinations of the specific gravity of the juice, or by analyses with the polariscope. There are various kinds of sugar-beet, and there are several improved sorts now at disposal. It is evident—and this is a matter worthy of the consideration of all the farmers in the country—that under normal conditions, *sugar-beet must pay better than wheat does, at present prices*. However, to ensure success, and to compete successfully with Continental producers, growers in this country must bestow their best land and their best care; they must learn that practically the selling value of the crop is to be regulated by the yield of sugar per acre, and this is the correct light in which to view the subject.

As regards *hardiness in times of drought*, the sugar-beet stands better than the ordinary mangolds, which have been almost a failure last year, even on heavy lands. In many fields, in which mangolds and sugar-beets were sown side by side, the mangolds did not appear, whilst the sugar-beets yielded a fair plant. Professor Church hopes that the important field experiments of 1884 will be continued during 1885, with every precaution to ensure success.

*Value of Sugar-beet as Cattle Food.*—Most satisfactory have been the experiments in this direction, and chemical analysis explains the superiority of sugar-beet over other roots, for feeding purposes; whilst mangolds usually contain 90 per cent. of water, and swedes and white turnips often more, sugar-beets generally average about 81 per cent. A crop of sugar-beet, although its gross weight may not be much more than half that of other kinds of roots, will contain quite as much solid nutritive matter. It presents the further advantage of containing less of those saline matters which, without being useful in animal nutrition, tend by their removal from the soil, towards the exhaustion of the latter.—W. S.

## XVI.—BREWING, WINES, SPIRITS. Etc.

*A New or Improved Apparatus for Injecting and Mixing Fluid Carbonic Acid in Small Regulated Quantities with Beer and Sparkling Liquors.* Loventz Albert Groth. Eng. Pat. 10,437, July 22, 1884.

The object of this invention is to inject and mix fluid carbonic acid in small regulated quantities into beer, sparkling liquors, or mineral waters, in a safe and simple manner, and consists of a receptacle A for the fluid carbonic acid, a regulator B to regulate its flow, and a mixing chamber C, fig. 1. The receptacle A, which is placed above the regulator, is provided with an outlet at the bottom, to which is connected the pipe leading to the regulator B, which is placed just above the mixing chamber C. The regulator B consists of a strong bulb P, with narrow neck k, screwed and soldered to it, forming the spigot of the tap o, and by the opening e, can allow the carbonic acid to flow in any required quantity, or stop it entirely, by turning the bulb P, like an ordinary tap. The mixing chamber C is an ordinary air-tight one, strengthened if need be by iron bands, and provided with a mixer e and manometer m. The action is as follows:—The carbonic acid flows by means of the outlet in the receptacle through the pipe into the entering tube r u, of

the tap or regulator B, and through the opening *r*, into the bulb P, from whence it is allowed to flow by turning the said bulb into the lower pipe *q*, leading into the mixing chamber *c*, while by turning the mixer *e*, the

FIG. 1.

FIG. 2.

carbonic acid is mixed with the liquid contained therein. When it is required to inject fluid carbonic acid into beer casks, either for cooling or in order to press the beer up to the bar, the apparatus is simply connected to the cask as shown in fig. 3.—A. W.

FIG. 3.

FIG. 4.

called tank, *i.e.*, a small pond or pool surrounded by butts, and constituting the whole water supply for all purposes of the inhabitants, such as washing, bathing, and drinking. Very frequently also latrines are to be found on the very edge of the water tank, draining into it. By means of the gelatin cultivation, Koch detected the cholera bacilli in the water of such a tank, but only in the course of an epidemic, only one of many samples of water taken at the end of the epidemic yielding the bacilli. It is noteworthy that the cholera bacilli can only be kept active by being preserved from drying up. They remain capable of development in liquids for weeks, and everything appears to indicate that they can only become incorporated with the human body when they are in the moist state.—F. L. T.

## XVIII.—SANITARY CHEMISTRY, DISINFECTANTS.

*Communication of Cholera by Drinking Water.* Dingl. [252] Heft. 6.

DR. ROB. KOCH, the head of the German Scientific Commission for the Investigation of Cholera, has succeeded in discovering specific bacilli in the intestines of those dying of cholera both in Egypt and in Calcutta. By artificial cultivation in gelatin the cholera bacilli may be obtained free from others, and can be recognized with certainty by their form and characteristic properties. By gelatin cultivation, cholera bacilli were obtained in all cases from the evacuations of cholera patients, or from the contents of the intestines of those dying from cholera. On examining the contents of the intestines of other corpses in the same way, the specific bacilli were found invariably absent, thus showing that the cholera bacillus is not an ordinary inhabitant of the intestines. In 1870 the mortality in Calcutta was on the average 10.1 per 1,000. Since 1870 it has fallen to three per 1,000.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES.

*On the Constitution of Quinidine Derivatives.* Ludwig Knorr, Berl. Ber. 17, 2032.

THE author gives the name quinizine to a hypothetical base,

from which a number of new bodies may be derived. The first of these derivatives, methyl oxyquinizine, has already been described by the author (Berl. Ber. 17, 546), and has the constitution

It is obtained by the condensation of equal molecules of phenylhydrazine, and aceto-acetic ether, thus:

The reaction takes place in two stages; in the cold, water is eliminated and phenylhydrazine aceto-acetic ether formed, and this on heating yields alcohol and methyl oxyquinizine. Of the two formulæ

by which phenylhydrazine aceto-acetic ether may be represented, the first is correct, for the hydrogen atom united to the second nitrogen atom in the hydrazine is still present in methyl oxyquinizine, and may easily be replaced by alcohol radicals. When the tertiary dimethyl oxyquinizine is heated to 200 with hydrochloric acid it yields aniline and methylamine; but methyl aniline is not formed. When distilled with zinc dust dimethyl oxyquinizine and methyl oxyquinizine form the same relative quantity of aniline, together with benzene and easily volatile bases, probably condensation products of methyl hydrazine and hydrazine with methyl ethyl ketone,

Here, again, methyl aniline was not obtained from dimethyl oxyquinizine. Lastly, the condensation products of the secondary hydrazines with aceto-acetic ether are not quinizine derivatives, but belong to another class of bodies. In the condensation of phenylhydrazine aceto-acetic ether, the ethoxy group, no doubt, unites with a hydrogen atom of the benzene ring to form alcohol, and not with the methylene group, for the latter remains in methyl oxyquinizine, for by the action of nitrous acid on methyl oxyquinizine the same isonitrosomethyl oxyquinizine is obtained as by the direct condensation of isonitroso aceto-acetic ether, with phenylhydrazine. All the properties and reactions of methyl oxyquinizine agree with the formula given above. It is both an acid and a base, but the acid properties disappear when the hydrogen of the imido group is replaced by an alcohol radical, and the base so obtained has powerful antifebrile properties. The methylene group has no longer the power of replacing hydrogen by metals, but it reacts with nitrous acid, and forms condensation products with aldehydes and ketones. Methyl oxyquinizine also resembles aceto-acetic ether in its tendency to form condensation products. Thus, when boiled with phenyl hydrazine, it forms dimethyl oxyquinizine with liberation of hydrogen.

The same compound is also formed by the condensation of diaceto-succinic ether, with phenyl hydrazine. When

treated with nitrous acid methyl oxyquinizine yields at first isonitroso-methyl oxyquinizine,

while dimethyl oxyquinizine forms a blue colouring matter, with liberation of two atoms of hydrogen, which, on reduction, is converted again into dimethyl oxyquinizine. In this reaction the nitrogen atoms of the imido groups combine to form an azo-compound, for if the hydrogen atoms of the imido groups in the quinizines are replaced by alcohol radicals, colouring matters are not formed by nitrous acid. When the hydrogen in the methylene group of simple quinizine derivatives is replaced by alcohol radicals, such azo-compounds are also formed; isonitrosomethyl oxyquinizine, however, yields an oxidation product with nitrous acid, probably

which, like the isonitroso compound and methyl oxyquinizine, is converted by nitric acid into the diquinizine blue. In the nomenclature of the quinizine derivatives the author adopts Baeyer's recommendations, and represents the atoms in the benzene, pyridine and imido groups, by the symbols B, Py and Az respectively, thus—

while the carbazine group  $R_1-N-NH$

is indicated by the termination *azine*. Accordingly, the author would call phenyl hydrazine aceto-acetic ether, phenylazine aceto-acetic ether. *Methylated methyl oxyquinizine (Antipyrene)*. The compound  $C_{10}H_{12}N_2O$  (Berl. Ber. 17, 549) is undoubtedly az-methyl-Py-1, methyl 3, oxyquinizine, and is isomeric with the dimethyl oxyquinizine obtained from the tolyl-hydrazines (*loc. cit.*), and with the quinizine derivatives from methyl aceto-acetic ether. The compounds thus formed are B-1 methyl Py-1 methyl 3, oxyquinizine; B-3 methyl Py-1 methyl 3 oxyquinizine, and Py-1-2, dimethyl 3 oxyquinizine, and all of them have acid properties. The az-methyl compound is easily soluble in water, while methyl oxyquinizine is almost insoluble.

*Physiological Action of Dimethyl Oxyquinizine (Antipyrene)*. This subject was investigated by Prof. Fileme (Zeitschr. für Klinische Medizin, VII., part 6). The substance is to be recommended as a febrifuge on account of its solubility and cheapness, and its powerful action, with no deleterious after effects. It is manufactured by Messrs. Meister, Lucius and Brünig, in Höchst, under the name "antipyrene." It cannot be employed for malaria. The physiological investigation of the antipyrene obtained from dimethyl oxyquinizine is interesting, for it contains two quinoline groups, like quinine. Ferric chloride colours an aqueous solution of antipyrene

deep red, and nitrous acid produces a blue green colouration, or if concentrated, green crystals, an isonitroso compound being formed. One part in 100,000 may be recognized by the ferric chloride reaction, and 1 in 10,000 by nitrous acid. Antipyrine forms condensation products with aldehydes, and a crystalline nitroantipyrine with nitric acid.

**Isonitroantipyrine.**— $C_{11}H_{11}N_3O_2$  was obtained in green crystals by treating an acid solution of antipyrine with a solution of nitrite. It is insoluble in water and dilute acids, soluble in alkalis and acetic acid, less so in alcohol, and difficultly soluble in chloroform and ether. Excess of nitrous acid has no reaction on it. By reduction of its solution in acetic acid a colourless oil is formed, which becomes red on oxidation. Nitroantipyrine yields the same products, which are probably amido- and oxyantipyrine.

**Nitroantipyrine.**—Concentrated nitric acid, previously boiled, dissolves antipyrine, and on warming forms a blood-red solution, from which water precipitates white needles of nitroantipyrine,  $C_{11}H_{11}N_3O_5$ .

The crystals melt at  $270^\circ$  to  $280^\circ$ , and are insoluble in water and alkalis, and but slightly soluble in concentrated hydrochloric and nitric acids.

**Benzyldiacetantipyrine.**  $C_{20}H_{25}N_3O_2$  is formed by adding concentrated hydrochloric acid to a solution of antipyrine in oil of bitter almonds. The hydrochloride crystallizes from dilute hydrochloric acid in long silky needles, from which caustic soda liberates the base. It may be crystallized from alcohol or ether. Its constitution is probably—

Nitrous acid has no action on it, therefore the condensation probably takes place in the methylene groups.

When antipyrine is heated with hydrochloric acid to  $200^\circ$  it is completely decomposed—methylaniline, aniline and ammonia being formed. When distilled with zinc dust a red oil was obtained. On fractionation a portion distilled between  $80^\circ$  and  $90^\circ$ , another between  $180^\circ$  and  $185^\circ$ ; but the greater part boiled above  $300^\circ$  with decomposition. The first portion consisted of benzene and an oil, boiling at  $86^\circ$  to  $87^\circ$ , containing 25 per cent. of nitrogen, probably methylethyl ketone.

A similar oil was obtained by distilling methyl oxyquinizine with zinc dust. The second fraction was pure aniline. The third forms a crystalline picrate, but has not yet been investigated.

**Action of Nitrous Acid on Methyl Oxyquinizine.** A brown oil was obtained, which solidified in yellow needles. It crystallized from acetic acid, and melted at  $137^\circ$ . Its composition was found to be  $C_{10}H_{10}N_2O_2$ . The same substance, melting at  $157^\circ$ , was obtained by direct condensation of isonitrosoacetacetic ether with phenylhydrazine. It is therefore isonitroso-methyl oxyquinizine.

It dissolves with difficulty in water and acids, easily in hot glacial acetic acid and alcohol, and is moderately soluble in ether. It is a strong acid. It begins to sublime at  $100^\circ$ , and decompose above its melting point.

Through an inadvertency, the continuation of this abstract is to be found on page 63, column 1, commencing with the heading *Isonitroso-methyl oxyquinizine*.

*On the Action of Diacetosuccinic Ether on Phenylhydrazine.* Ludwig Knorr and Carl Bulow. Berl. Ber. 17, 2057.

The following substances were obtained by the condensation of these bodies:—

**Phenylazine-acetosuccinic Ether.**

**Diphenylazine diacetosuccinic Ether.**

**Dimethyloxyquinizine.**

The second compound is the most easily prepared. It is formed by mixing the alcoholic solutions, or by fusing the reacting substances on the water bath. At  $180^\circ$  the first and third compounds are formed, from which the first may be extracted with alcohol, leaving the third as a crystalline powder. The second compound is converted into the third by heating in toluene to  $180^\circ$ . The first could not be converted into the second.

**Phenylazine-acetosuccinic ether.** The alcoholic solution obtained as above described was treated with water, when an oil was deposited. The ethereal solution of the oil was shaken with acid, then with alkali, and the residue after evaporation dissolved in alcohol and precipitated as before. The oil solidified rapidly and was crystallized from acetic acid or petroleum spirit. The crystals melt at  $91^\circ$  and have the composition  $C_{15}H_{15}N_3O_2$ .

**Diphenylazine-diacetosuccinic ether** was obtained by adding a solution of 5 grams, diacetosuccinic ether in alcohol to an aqueous solution of 5 grams, phenylhydrazine hydrochloride and 12 grams, sodium acetate. The substance was deposited on warming the mixture in fine crystals which have the composition  $C_{25}H_{25}N_3O_4$ . The substance was better prepared by melting the reagents together. The ether is insoluble in water, alcohol, acids, or alkalis.

**Di-methyloxyquinizine** was obtained as already described. It melts above the boiling point of sulphuric acid, and after drying at  $120^\circ$  is powerfully electric. It has the composition  $C_{10}H_{10}N_2O_2$ . It is identical with the substance prepared by the action of phenylhydrazine on methyl oxyquinizine. It yields diantipyrenes and a quinizine blue. The diantipyrene melts at  $250^\circ$  and has the composition  $C_{22}H_{22}N_2O_2$ . The solution of the sodium salts of both di-methyl oxyquinizines give precipitates of the same colour with the solutions of most heavy metals.—S. Y.

*On the Action of Ethyl succinylsuccinate on Phenylhydrazine.* Ludwig Knorr and Carl Bulow. Berl. Ber. 17, 2053.

KNORR has already shown that the chief product of this action is a yellow body of the composition of  $C_{20}H_{16}N_4O_2$ , which is formed thus—

(Berl. Ber. 17, 546). It is evidently a quinizine derivative, and must be diquinizimohydrobenzene. By varying

the conditions of experiment, the following substances have now been prepared by the authors:—

Ethyl phenylazine-succinylsuccinate.

Ethyl Diphenylazine-succinylsuccinate.

Ethyl Phenylazinequinizinohydrobenzencarbonate.

Diquinazinohydrobenzene.

The last two bodies exhibit the characteristic properties of methyloxyquinizine. The condensation products yield no colouring matters. When an excess of succinylsuccinic ether is warmed with an alcoholic solution of the phenylhydrazine reagent prepared by E. Fischer's method, a small quantity of ethyl phenylazine-succinylsuccinate is formed in addition to diquinazinohydrobenzene. After purification by precipitation of the alcoholic solution with water, the substance crystallized in needles, which melted at 159–160°, and which have the composition  $\text{C}_{18}\text{H}_{12}\text{O}_5\text{N}_2$ .

When two equivalents of hydrazine dissolved in toluene were heated for several hours with one equivalent of ethyl succinylsuccinate and a little acetic acid, the second compound described above was formed, together with the last two. It was separated by boiling with alkali, and formed a yellow crystalline powder, melting at 205–206°. Its composition is  $\text{C}_{22}\text{H}_{14}\text{N}_4\text{O}_4$ . It forms a carmine-red solution with acids. It is destroyed by boiling with strong acids, and gives no colouring matter with nitrous acid.

The ethyl diphenylazine-succinylsuccinate was separated from the diquinazinohydrobenzene by boiling with toluene. It crystallizes from toluene in yellow needles, which melt at 211–212°, and have the composition  $\text{C}_{22}\text{H}_{16}\text{N}_4\text{O}_5$ . Its properties are intermediate between those of the second and fourth compounds. It is insoluble in water and alcohol; its alkaline solution is yellow; its acid solution a light rose colour. The acid solution oxidises in the air, but more quickly with nitrous acid, forming emerald green, or, if dilute, a blue solution, which on further oxidation becomes brown. The last two substances evolve a green vapour on heating.

Diquinazinohydrobenzene was best prepared by heating an alcoholic solution of the reacting substances. The product separates slowly as a yellow crystalline powder, and the reaction is complete after heating for about a day. When prepared in this manner it is free from the

other substances. It forms a purple solution with alkalis and ammonia, and is reprecipitated by acids and carbonic anhydride. It dissolves in strong acids, and is precipitated again by water. It forms substitution products corresponding with the antipyridines, and gives a blue colouring matter by oxidation. When the neutral sodium salt is boiled for several hours with methyl alcohol and excess of methyl iodide, dimethyldiquinazinohydrobenzene is precipitated in yellow needles, which have the composition  $\text{C}_{22}\text{H}_{14}\text{N}_4\text{O}_2$ . It is easily soluble in acids, less so in chloroform and toluene, but is difficultly soluble or insoluble in most substances. The chloroform and toluene solutions exhibit a fine fluorescence resembling uranium glass. The diethyl compound was also prepared.

Diquinazinohydrobenzene blue was prepared by acidifying an alkaline solution of diquinazinohydrobenzene and a nitrite. It separates in blue flakes, which were extracted with chloroform, and washed with ether. It has the composition  $\text{C}_{20}\text{H}_{14}\text{N}_4\text{O}_2$ , and is formed thus:—

Since dimethyldiquinazinohydrobenzene is unaltered by nitrous acid, the formation of the colouring matter is analogous to that of diquinizine blue. The substance sublimes with partial decomposition, forming purple-red vapours and a blue sublimate of the unaltered colouring matter. The same sublimate is formed by heating diquinazinohydrobenzene.—S. Y.

*On the Action of Substituted Acetoacetic ethers on Phenylhydrazine.* Ludwig Knorr and Albert Blank, Berl. Ber. 17, 2, 649.

*Methylacetoacetic ether and phenylhydrazine.* Equal parts of the two substances were heated to 140°, and the product poured into ether, from which the condensation product was precipitated. It melted at 127 to 132°, and had the composition  $\text{C}_{11}\text{H}_{12}\text{N}_2\text{O}$ . It is isomeric with antipyridine, and is Py-1,2 dimethyl-3 oxyquinizine

Like methyloxyquinizine it is an acid and a base, and yields an antipyridine, melting at 84° when heated to 100° with methyl iodide and methyl alcohol. Excess of phenyl hydrazine does not give a diquinizine. Oxidising agents, such as nitrous acid, convert it into an indifferent body, which must have the constitution

for the corresponding antipyridine does not exhibit the reaction. This body, azo-dimethyl-oxyquinizine, melts at 164°, but cannot be distilled. It crystallizes from hot glacial acetic acid and alcohol. It is insoluble in water, acids and alkalis, but dissolves in concentrated sulphuric acid. It was analysed.

*Ethylacetoacetic ether and phenylhydrazine* yield Py-1 methyl-2 ethyl-3 oxyquinizine,  $\text{C}_{12}\text{H}_{14}\text{N}_2\text{O}$ , melting at 108°. It dissolves easily in chloroform, alcohol, and benzene, less so in ether and petroleum spirit. It crystallizes from hot water in needles, containing one molecule of water which is given up at 80°. The hydrated and anhydrous substances were analysed. Azo-methyl-ethyl-oxyquinizine was prepared like the dimethyl compound. It melts at 160°, and has the composition  $\text{C}_{14}\text{H}_{16}\text{N}_2\text{O}_2$ .

*Acetosuccinic ether and phenylhydrazine* form a condensation product which melts at 80°, and has the composition  $\text{C}_{14}\text{H}_{12}\text{N}_2\text{O}_4$ . It is phenylazine-acetosuccinic ether. At 150° it gives up alcohol and forms methyl-

oxyquinizine acetic ethers. (Py-1 methyl-3 oxyquinizine Py-2 acetic ether). Recrystallized from petroleum spirit, it melts at  $138^{\circ}$ , and has the composition  $C_{20}H_{16}N_2O_5$ . By saponification with 10 per cent. sulphuric acid methyl oxyquinizine acetic acid is formed. It crystallizes from water in needles, which melt at  $178^{\circ}$ , and have the composition  $C_{16}H_{12}N_2O_5$ . Its constitution is—

(Py-1 methyl-3 oxyquinizine-Py-2 acetic acid).—S. Y.

*Isonitrosomethylidioxiquinizine*,  $C_{16}H_{12}N_2O_5$ , was obtained as a black oil by acidifying an alkaline solution of methyloxyquinizine and sodium nitrite. It was extracted with ether, and crystallized from alcohol in colourless prisms. It is Az-oxy-Py-1 methyl 2 isonitroso-3 oxyquinizine :

It is insoluble in acids, but dissolves in alkalis. With nitric acid it yields diquinizine blue. When methyloxyquinizine is warmed with previously boiled concentrated nitric acid an oil is deposited, but is destroyed by further oxidation. Water was therefore immediately added, and the substance extracted with ether. The solution, however, rapidly became blue owing to the formation of a substance having the properties of diquinizine blue. The colourless product was not obtained pure, but it yields isonitrosomethylidioxiquinizine with nitrous acid, and it is therefore probably methyloxyquinizine :

*Action of Phenylhydrazine on Methyloxyquinizine.* When a solution of methyloxyquinizine in phenylhydrazine is boiled, rhombic crystals are deposited, which are insoluble in almost all solvents. The carefully purified substance was analysed, and was found to have the composition  $C_{26}H_{18}N_4O_2$ , and not  $C_{26}H_{18}N_4O$  as previously stated. As the same substance is formed by the condensation of diacetosuccinic ether with phenylhydrazine its constitution must be—

and it is di-methyloxyquinizine. In this reaction the hydrazine acts as an oxidising agent, removing hydrogen from the methyloxyquinizine, and forming aniline and ammonia thus :

Almost the theoretical yield of di-methyloxyquinizine is also obtained by heating two molecules of acetoacetic ether with three molecules of phenylhydrazine. The reaction appears to be a general one for all quinizine derivatives in which the methylene group is unaltered ; thus  $\beta$ -naphthylmethyloxyquinizine gives a di- $\beta$ -naphthylmethyloxyquinizine. By heating di-methyloxyquinizine with methyl iodide and methyl alcohol, di-antipyrine is formed. It melts at  $250^{\circ}$ , and has the composition  $C_{22}H_{22}N_2O_2$ . The corresponding ethyl compound melts between  $240^{\circ}$  and  $250^{\circ}$ . The same compound may be prepared by boiling the alcoholic iodides with a solution of di-methyloxyquinizine in sodium ethylate. They are difficultly soluble in water, and their salts crystallize well.

*Diquinizine Blue.* When di-methyloxyquinizine is treated with nitrous or nitric acid a blue substance, having the composition  $C_{20}H_{16}N_2O_2$ , is obtained, thus  $C_{20}H_{16}N_2O_2 + O = H_2O + C_{20}H_{16}N_2O_3$ . The reaction takes place in the imido groups, for the anti-pyridines do not give similar bodies, and the constitution of diquinizine blue must be—

It is insoluble in water and dilute acids and alkalis, and difficultly soluble in alcohol and ether, but dissolves easily in chloroform and concentrated sulphuric acid, forming indigo-blue coloured solutions, the spectra of which resemble that of indigo. It has no affinity for fibres. By reduction it forms di-methyloxyquinizine. It may be prepared from methyloxyquinizine, isonitrosomethylidioxiquinizine or isonitrosomethylidioxiquinizine by the action of nitrous acid. The authors show the following analogies between the quinizine derivative and other classes of substances. Their relation to phenylsulphocarbazine (Annalen 212, 332), and to the indazole compounds (Annalen 221, 261) is shown by the carbazine group contained in the quinizine compounds. Thus :

Phenylsulphocarbazine

C

S

M.P. 129.

Isonitrosomethylidioxiquinizine

C-CH<sub>3</sub>

M.P. 113.

Methyl oxyquinizine.

M.P. 127.

The properties of these compounds are similar in many respects. Isonitrosomethylidioxiquinizine is formed by the condensation of orthoamidooacetophenone with hydrazines. The quinoline group in methyloxyquinizine may be considered as a derivative of tetrahydroquinoline. This view is supported by the physiological action of the compounds, and the synthesis of  $\gamma$ -oxyquinazoline from aniline and acetoacetic ether (Berl. Ber. 17, 530). The want of similarity in the chemical properties of methyloxyquinizine and tetrahydroquinoline is explained by the fact that in the former compound the methylene group remains intact. The analogy between methyloxyquinizine and pseudooxindol is shown by their constitution—

NH

Both substances contain acid imido groups. They form isonitroso compounds with nitrous acid and condensation products with aldehydes. In both the carbon of the methylene group tends to condense to form double molecules, which easily give blue coloured products. The author compares the formation of diquinizine blue with that of indigo, as described earlier by Baeyer (Berl. Ber. 15, 54), thus :

The properties of isonitrosomethoxyquinizime and isonitrosopyrroline also bear great resemblance to those of  $\beta$ -naphthoquinonoxime :

—S. Y.

*On the Cinchona Alkaloids.* W. J. Comstock and Wilhelm Königs. Berl. Ber. 17, 1984.

WHEN cinchonine is treated with phosphorus pentachloride and phosphorus oxychloride, cinchonine chloride,  $\text{C}_{19}\text{H}_{27}\text{N}_2\text{OCl}$  is formed (Berl. Ber. 13, 285), and on boiling this substance with alcoholic potash cinchene,  $\text{C}_{19}\text{H}_{26}\text{N}_2$ , is obtained (Berl. Ber. 14, 1852). Cinchene when heated to 220° to 230° with concentrated hydrochloric acid yields methyl chloride, ammonia and apocinchene  $\text{C}_{17}\text{H}_{17}\text{NO}$ . The authors, continuing the work, have experimented similarly on quinine and cinchonidine. A base was obtained from cinchonidine which appeared to be identical with cinchene, while quinine yielded a similar base which contained the elements of one molecule of water less than cinchene.

Cinchonine chloride was obtained by heating 30 grm. dry cinchonine hydrochloride with 40 grm. phosphorus pentachloride and 200 grm. phosphorus oxychloride to 50° to 60° until a drop, treated with ammonia remained clear when shaken with ether. After decomposing the phosphorus compounds the cooled mixture was treated with excess of ammonia, when, after standing, cinchonine chloride was deposited as a crystalline white mass. It was dried, extracted with warm ether and filtered after cooling. The yield was about 75 per cent. The residue after evaporating the ether was boiled for about 24 hours with an equal weight of caustic potash and four or five times the quantity of alcohol. The alcohol was evaporated, the residue treated with water and extracted with ether. The substance was purified by boiling with tartaric acid and animal charcoal, and decomposing the crystalline tartrate with soda. The yield was about 50 per cent. of the cinchonine hydrochloride. The base after crystallization from petroleum ether melted at 123° to 125°. It was analysed.

When heated with hydrochloric acid of sp. gr. 1.19 for eight hours, cinchene yielded apocinchene as a yellow difficultly soluble hydrochloride, which after purification was treated with ammonia. The pure base crystallizes from alcohol in colourless needles melting at 209°. The composition  $\text{C}_{17}\text{H}_{17}\text{NO}$  was proved by analysis. Oxyapocinchene was prepared from apocinchene by treatment with fused potash. The pure substance, melting at 267° was analysed, and its composition found to be  $\text{C}_{18}\text{H}_{17}\text{NO}_2$ .

*Cinchonidine Chloride*,  $\text{C}_{19}\text{H}_{21}\text{N}_2\text{OCl}$ .—The hydrochloride was treated like cinchonine hydrochloride, and the crude cinchonidine chloride dissolved in ether, dried with potash, filtered, and treated with ligroin until the solution became turbid. The substance crystallized on standing, and after purification melted at 108° to 109°. The composition was proved by analysis. When treated with alcoholic potash the cinchonidine chloride yielded a base, cinchonidine,  $\text{C}_{19}\text{H}_{20}\text{N}_2$ . It was purified in the same manner as cinchene, which it closely resembled, except

that its melting point was lower, 116° to 118°. The crystalline form of both compounds was found by Dr. Grunling to be identical. When boiled with hydrochloric acid cinchonidine yielded apocinchene, melting at 209°. Cinchonidine and cinchene thus appear to be identical, and the isomerism of cinchonidine and cinchonine probably depends on the different arrangement of the elements of the molecule of water added to cinchene to form these compounds.

*Quinine Chloride*  $\text{C}_{20}\text{H}_{26}\text{N}_2\text{OCl}$ .—This substance was prepared like the preceding chlorides, but chloroform was employed in place of phosphorus oxychloride. After purification by solution in benzene, and precipitation with ether, the chloride melted at 151°. It was analysed. The solution in dilute sulphuric acid exhibits no fluorescence, and the colour reaction with chlorine water and ammonia is not so intense as with quinine.

*Quinine*,  $\text{C}_{20}\text{H}_{26}\text{N}_2\text{O}$ , was prepared from quinine chloride by boiling with alcoholic potash. It was purified by conversion into the double chloride of zinc and quinine, which could be crystallized. The base was set free by addition of caustic soda, dissolved in ether and allowed to crystallize. It melted at 81 to 82°, and contained two molecules of water of crystallization, which were removed at 100°. Both the hydrate and the anhydrous base were analysed. The sulphate is easily soluble and is fluorescent.

*Oxidation Products of Cinchene, Cinchonine and Quinine.* When cinchonine is oxidised with chromic acid and dilute sulphuric acid, carbon dioxide, formic acid and cinchonic acid are formed, while quinine yields quinic acid. The constitution of these acids is well understood, but that of the simultaneously formed by-products is unknown, and its discovery might be expected to throw some light on the groups containing the second nitrogen atom in cinchonine and quinine.

Very little success has attended the attempts to obtain well characterized products from the mother liquors from cinchonine and quinic acids. Weidel and Hazura (Wiener Monatshefte, 1882, 770) prepared from the mother liquor from cinchonine acid very small quantities of nitroxyquinoline, bethylpyridine, quinoline and pyridine. Neither these results nor those of Wischnegradsky and Von Oelsner de Couinek on the action of fused potash throw much light on the question.

The authors oxidised cinchene with chromic acid and dilute sulphuric acid, when carbon dioxide was evolved and cinchonic acid formed. After removal of the chromium with barium hydrate and carbon dioxide, the copper salt of cinchonic acid was prepared and removed by filtration. The filtrate still contained a large quantity of organic matter, from which no definite product could be obtained in the ordinary way. It was therefore treated after removal of the excess of copper, with bromine water until a yellow flocculent precipitate ceased to be formed.

When boiled with sulphurous acid this precipitate became nearly white, while that obtained by brominating cinchonic acid dissolves in aqueous sulphurous acid. The decolourised precipitate was insoluble in water and dilute acids, but dissolved easily in caustic soda. It crystallized well from alcohol or glacial acetic acid. The yield of the crude product was 5 per cent. The same substance was obtained from the mother liquor from cinchonic acid. After drying at 150° the substance was found by analysis to have the same composition as tribromoxylepidine  $\text{C}_{19}\text{H}_{17}\text{Br}_3\text{ON}$ . It does not melt at 280°, and may be sublimed in small quantities. When boiled with sodium amalgam and water small quantities of quinoline and hydroquinoline are formed, and it yields a very little of the former compound when heated with a solution of hydriodic acid in glacial acetic acid. The behaviour of the compound points to its being a tribromoxylepidine with the acid hydroxyl radical in the benzene or pyridine group. Lepidine as well as quinoline is formed when cinchonine is fused with alkali, and cinchonic acid may be considered as a derivative of lepidine, for it is obtained by the oxidation of the base. Hence tribromoxylepidine and cinchonic acid are probably formed from the same groups in cinchonine.

An easily soluble bromine derivative was also obtained from the mother liquor from cinchonine acid. When the strongly acid filtrate from the tribromoxylepidine was evaporated brown crystals were deposited. They were obtained after purification in colourless prisms, which, after drying at  $120^{\circ}$  to  $130^{\circ}$ , were found to have the composition  $C_{19}H_{20}Br_2NO + \frac{1}{2}H_2O$ . On treating the warm aqueous solution with nitric acid and silver nitrate half the bromine was precipitated. On boiling for some time the second atom of bromine was also removed. After removal of one atom of bromine the substance was treated with gold chloride and the gold salt analysed. It had the composition  $C_{19}H_{20}BrNO \cdot HCl \cdot AuCl_3 + H_2O$ . The dibromo-compound melts at about  $250^{\circ}$  but blackens and evolves gas. The aqueous solution is acid and remains so after boiling with ammonia. Neither ammonia, potash, nor sodium acetate or carbonate produces precipitates. Both phosphomolybdic acid and a solution of mercuric chloride in potassium iodide give precipitates. The substance appears to have the character of a quaternary ammonium salt, which would not be decomposed by dilute alkali. Moist silver oxide appears to form the hydroxide. This would justify the view that cinchonine contains a hydrated pyridine or quinoline group, with a methyl radical combined with the nitrogen. The mother liquor from quinine acid, when treated with bromine water, gave a yellow precipitate which, however, dissolved easily in sulphurous acid, and was therefore not tribromoxylepidine. The filtrate from the yellow precipitate, after evaporation, yielded crystals identical with the second bromine derivative described above, and the yield was about the same. This derivative therefore appears to contain the second nitrogen atom of cinchonine and quinine. Cinchonine  $C_{19}H_{22}N_2O$ , and quinine accordingly on oxidation yield cinchonine acid and quinine acid with 10 and 11 atoms respectively of carbon, and a second product with 9 atoms of carbon, which when treated with bromine water forms the body  $C_{19}H_{20}Br_2NO$ .

*Dibromocinchonine*.—This substance has been prepared by Laurent (Annalen, 72, 305) and Kopp (Jahresb. 1876, 822) by boiling cinchonine hydrochloride with bromine. The authors prepared it by treating a cooled solution of 20grms. cinchonine in 320grms. chloroform and 160grms. alcohol with 21grms. bromine dissolved in 80grms. chloroform. The substance was crystallized from a mixture of carbon bisulphide and alcohol, and was then analysed. Its composition is  $C_{19}H_{20}Br_2N_2O + H_2O$ . The crystals when warmed appeared to give up hydrobromic acid slowly. When oxidised with chromic acid and dilute sulphuric acid, cinchonine acid, and hydrobromic acid were formed. On boiling the substance with alcoholic potash a base free from bromine was obtained in the form of colourless needles, melting at  $202^{\circ}$  to  $203^{\circ}$ . It appeared to be a dehydrocinchonine  $C_{19}H_{20}N_2O$ . Dibromocinchonine was prepared from pure cinchonine, but could not be obtained from cinchotine.—S. Y.

contained, it finds its way through the perforations already mentioned into the liquid in the outer washing vessel. The gas here ascends in a second stream of

minute bubbles, so being washed a second time. Very perfect washing is thus attained, and the apparatus is especially useful where a rapid stream of gas is required.

—E. G. C.

## New Books.

CHEMISCH-TECHNISCHE ANALYSE. Handbuch der analytischen Untersuchungen zur Beaufsichtigung des chemischen Grossbetriebs. Unter Mitwirkung von L. Aubry, W. Avenarius, C. Deite, M. Delbrück, L. Drehschmidt, C. Engler, R. Gnehm, C. Heinzerling, A. Hilger, A. Jena, A. Ledebur, C. Lintner, S. Marasse, W. Michaelis, F. Muck, M. Müller, J. Philipp, C. Rudolph, H. Schwarz, P. Wagner, A. Weinhold, H. Zwick; herausgegeben von Dr. JULIUS POST, Professor an der Universität zu Göttingen. Mit 184 in den Text eingedruckten Holzschnitten. Braunschweig: Druck und Verlag von Friedrich Vieweg und Sohn; 1882.

This excellent work, well known in Germany, is the result of the compilation of details connected with various branches of the chemical industries, written and furnished by the above named eminent authorities, each an expert in his several branch, and each representing a special branch in the present work. This is an 8vo. volume, bound in the usual yellow paper cover characteristic of Messrs. Vieweg's publications, and containing 1,068 pages of subject-matter, a copious alphabetical index, 184 wood-cuts and a complete table of contents, from a list of the headings of which a fair idea of the nature of the matter treated in the book may be gathered. These headings with their corresponding numbers, also indicate the chapters devoted to the subjects mentioned: I., Wasser; II., Untersuchung der Brennstoffe auf ihre Bestandtheile; III., Ermittlung des Heizwerthes der Brennstoffe; IV., Pyrometrie; V., Leuchtgas; VI., Die festen und flüssigen Kohlenwasserstoffe des Mineralreichs; VII., Die Metalle; VIII., Anorganische Säuren, Alkalisalze und Chlorkalk. (Rohstoffe und Erzeugnisse des Leblanc-Processes, der Salpeter-, Potaschen-, u. s. w.-Fabrikation); IX., Handelsdünger; X., Explosiv- und Zündstoffe; XI., Kalk, Cement (und Gyps); XII., Fette; XIII., Stärke, Zucker und Gährungsgewerbe; XIV., Bier; XV., Spiritus (und Presshefe); XVI., Essig, Essigsäure, Acetate und Holzgeist; XVII., Leder und Leim; XVIII., Metallsalze; XIX., Farbstoffe und zugehörige Industrien; XX., Thonwaren; XXI., Glas. The attention of dyers and colourists may be invited to the tests for the coal-tar colours given in chapter XIX., both alone and on the fibre. The price of the work is 26s., (26 Mark).

## XXII.—GENERAL ANALYTICAL CHEMISTRY.

A Double-Action Gas Wash-Bottle. Dr. F. Allihn. Dingl. Polyt. Jour. 254, 118.

THIS apparatus consists of an inner cylindrical washing-flask, fused on to the longer tube of an outer wash-bottle. Both the longer and the shorter tubes of the latter are fused to its hollow stopper. In the upper half of the smaller washing vessel is a ring of perforations, shown in the figure annexed. To use the apparatus, the bottle is about three-quarters filled with the washing fluid, and then gently inclined, so that the liquid can enter and fill the inner vessel, up to the ring of perforations. The long tube, which reaches nearly to the bottom of the cylindrical flask is open at its lower end, but it has, a few millimetres above, two rows of very small openings, through which the gas, broken up into minute bubbles, enters the inner vessel. After passing through the washing fluid therein

**THE ART OF LEATHER MANUFACTURE**, being a practical Handbook in which the operations of Tanning, Currying, and Leather dressing are fully described, the principles of Tanning explained, and many recent processes introduced, as also methods for the Estimation of Tannin and a description of the Arts of Glue boiling, Gut dressing, etc. By ALEXANDER WATT, Author of "The Art of Soap-making," "Electro Metallurgy," etc., etc. London: Crosby, Lockwood and Co., 7, Stationers' Hall Court, Ludgate Hill; 1885. [All rights reserved.]

This is an 8vo. volume, bound in cloth, and containing 412 pages of subject-matter, the introduction included. Seventy-six wood-engravings are interspersed in the text and the work concludes with some tables of decimal weights and measures, a list of works for reference and a full alphabetical index. From the table of contents, indicating the manner of subdivision of the text into chapters, the following headings have been abstracted and these indicate more essentially the nature of the matter treated of: Chapter I., chemical theory of the tanning process; II., the skin; III., hides and skins; IV., tannin or tannic acid; V., gallic acid; VI., gallic fermentation; VII., tanning materials; VIII., estimation of tannin; IX., preliminary operations; X., depilation or unhairing skins and hides; XI., raising or swelling; XII., tanning butts for sole leather; XIII. and XIV., tanning processes; XV., tanning by pressure; XVI., quick tanning; XVII., manufacture of harness and upper leather; XVIII., American tanning; XIX., hemlock tanning; XX., tanning by electricity; XXI., chemical tanning; XXII., miscellaneous processes; XXIII., cost of tanning; XXIV., manufacture of light leathers; XXV., dyeing leather; XXVI., manufacture of white leather; XXVII. and XXVIII., currying; XXIX., machinery employed in leather manufacture; XXX., embossing leather; XXXI., fellmongering; XXXII., parchment, vellum and shagreen; XXXIII., gut dressing; XXXIV., glue boiling; XXXV., utilisation of tanners' waste.

16715 J. Donald, Glasgow. Improvements in purifying sulphuric acid. December 20

- 16717 W. S. Richardson and W. J. Grey. Improvements in the method of treating calcium chloride for the production of bleaching powder, and other materials therefrom. December 20  
16711 F. W. Scott, London. Improvements in apparatus for obtaining cold dry air. December 20  
16745 E. Levett, London. Improvements in apparatus for effecting the subsidence of solid matters in suspension in liquids. December 20  
16750 H. Green, London. Means for effecting tight closure of gas retorts. Complete specification. December 20  
16759 R. Lehmann, London. Improvements in the manufacture of hydrogen. Communicated by J. Oettli, Cossonay. December 20  
16761 W. R. Lake, London. An improved composition or size chiefly designed for imparting brilliancy to hats. Communicated by S. Coste, Paris. December 20  
16763 J. Burnett, London. Improvements in the manufacture of bleaching powder. December 20  
16769 W. G. Strype, London. Improvements in the production of hydrates of baryta and strontia. December 20  
16785 W. A. Dyer, London. Arresters or interceptors for desiccating machines, vacuum pans, and concentrators, and other similar apparatus. December 22  
16789 W. G. Strype, London. Improvements in the production of caustic soda and of carbonate of soda. December 22  
16805 F. Wynne and L. S. Powell, London. Improvements in the production of a carbonisable material for the manufacture of carbons for electric lamps, and in the manufacture of this material for light and other purposes to which it is applicable. December 22  
16806 C. Lehofer, London. Manufacture of human excrement manure in dry and valuable condition. December 22  
16831 J. Soucrville and W. H. Y. Webster, Forest Hill, Surrey. A slow combustion smokeless gas furnace. December 23  
16847 F. J. Harrison, London. An improved cleansing compound. December 23  
16852 J. Page, London. Improvements in furnaces for close annealing steel, iron, or metals. December 23  
16855 M. Banks, London. A new or improved method of plating silver with gold. December 23  
16885 I. Levinstein, London. Improvements in apparatus for charging beer or other liquids with carbonic acid gas or other gases, and discharging the liquid from its containing vessel. December 24  
16887 H. Bassett, London. Improvements in fireplaces or furnaces for heating pottery, brick, or like kilns or ovens. December 24  
16891 T. H. Hodges, London. Improvements in machines for manufacturing paper, leather-board, and mill-board. December 24  
16892 W. L. Wise, London. New or improved manufacture of waterproof clothing. Communicated by J. A. Thierry-Delattre, Rheims. December 24  
16893 J. Gillespie, London. Improvements in the bricks and the internal walls of furnaces, and in concrete walls. December 24  
16890 W. Smith, Dublin. Improvements in the manufacture of Portland cement. December 27  
16897 T. Bowen, London. Improvements in the purification of tin and its alloys, and in apparatus employed therein. December 29  
16898 J. Robbins, London. An improved artificial fuel. December 29  
16899 H. L. Pattinson, jun., London. Improvements in the manufacture of hydrates of barium and strontium. December 29  
17021 F. T. Bond, Gloucester. Pervious firebricks for lining fire grates. December 30  
17033 J. H. Johnson, London. Improvements in the manufacture of compound armour plates. Communicated by Marrel Brothers, Rive de Gier. December 30  
17039 R. Buchanan, London. Improvements in drying chambers for drying foundries' moulds and cores. December 30  
17045 W. R. Lake, London. An improved compound to be used as a substitute for ivory. Communicated by J. R. Edson, United States. Complete specification. December 30  
17053 J. Smith and P. W. Nield, London. Improvements in the treatment of vegetable fibres for the extraction of the extraneous matters therefrom. December 31  
17084 A. J. Marquand, E. Hancock, and J. R. Powell, London. The prevention of corrosion and removing of deposit in steam or other boilers. Complete specification. December 31  
17090 G. V. Barry, London. Improvements in the process of and apparatus for treating meass for extracting sugar therefrom. Communicated by G. Kottmann, New South Wales. Complete specification. December 31  
17097 J. S. Williams, Riverton, New Jersey, U.S. Improved processes, means, or apparatus for treating or working metals or other materials, and in apparatus or means employed therefor or in connection therewith. December 31  
17108 W. G. Little, London. Improvements in apparatus for carburising gas for lighting purposes. December 31

1885.

- 19 R. H. Ainsworth and E. B. Manby, London. Improvements in the construction of bleaching kiers. January 1  
22 J. H. Loder, Tolsteegingel, Netherlands. Improvements in the process of fermentation in order to prepare alcoholic solutions of aromatic colouring matters, and of aldehydic aromatic bodies. January 1

28 G. S. Parkinson, London. The preparation of roots into food. January 1

39 S. R. Hooper, London. Improvements in the manufacture of emulsion paints. Complete specification. Jan. 1

40 A. de Collobard, E. de Gobard and A. de la Roche, Paris. Improvements in the extraction of alcohol from coal. Jan. 1

46 P. Platt and J. M. Aitchison, London. Improvements in kilns for drying malt, hops, &c. Complete specification. January 1

47 J. R. Turnock, Loughor. Tinning circles, ovals, and such like plates. January 2

68 J. R. Turnock, Loughor. Multiplex tin plates,terne plates and sheets. January 2

86 H. Giesler, London. Improvements in apparatus for washing, scouring, bleaching, dyeing, steaming, drying, and otherwise treating fibrous material in the form of slubbing silvers rovings or yarn. January 2

91 C. Cochran, London. Improvements in the means and apparatus for desiccating the air supply to furnaces. Jan. 2

126 J. Norman, London. Improvements in filter presses. January 3

127 S. Briggs, London. Improvements in refrigerators for brewers, distillers, and other like uses. January 3

132 H. Hutchinson, London. Improvements in apparatus for generating gas. January 3

145 J. Tulloch and T. Tulloch, Glasgow. An improved incombustible composition for finishing the interiors of buildings. January 5

151 L. Q. Brin and A. Brin, London. The manufacture of anhydrous oxide of barium. January 5

146 L. A. Groth, London. A new or improved method of manufacturing halogen salts of aluminium and beryl. Communicated by H. Gracovet, London. January 5

157 L. Q. Brin and A. Brin, London. Improvements in the separation and obtainment of oxygen and nitrogen from atmospheric air. January 5

158 J. Berger Spence, London. Improvements in the manufacture of soap. January 5

159 J. Berger Spence, London. Improvements in the manufacture of soap by the utilisation of by-products. January 5

167 J. Rapiett, London. Improvements in utilisation and generation of by-products of galvanic batteries. Complete specification. April 4. Previously included in No. 5922, 1881.

211 J. C. Gilman and S. Spencer, London. Improvements in the treatment of grain to be used in brewing, distilling, and vinegar making. January 6

239 A. S. Jones, London. Improvements in and arrangements for treating and disposing of sewage. January 7

249 J. M. H. Muir, Salisbury, and T. Wrightson, Stockton-on-Tees. Improvements in the treatment of "basic cinder. January 7

256 E. Wilson, Exeter. A new method of manufacturing granulated soap. January 8

258 J. Jackson, Liverpool. Conveying and burning gas in connection with gas furnaces of steam-generators. January 8

261 T. D. Over, London. Improvements in the treatment of vat liquor for the elimination of sulphides and other impurities, and in the recovery and re-use of the reagents employed therein. January 8

274 H. Rhodes, London. Improvements in the means employed for cleansing or purifying and improving the quality of oils or greases, such as mineral oils, black, or recovered oils, seak oils, and the like. January 8

275 E. Passbury, London. Process and apparatus for drying colour-paste, and other strongly aqueous materials. January 8

287 C. D. Abel, London. An improved manufacture of compound metal plates, and apparatus or appliances for that purpose. Communicated by Billinger Hüttenwerke, Billigroon-Saar. January 8

304 J. Foulds and S. Tomlinson, Bradford. Crushing and reducing to powder stone, or other hard material. January 9

312 J. Sackerevell Gisborne, London. An improved anti-fouling and preservative composition for coating ships' bottoms, and iron and wooden structures generally. January 9

340 R. A. Rossborough, Liverpool. Improvements in the manufacture of faced or coated bricks, and in apparatus therefor. January 10

341 A. G. Manchester. Improvements in or relating to printing and dyeing cotton fabrics. January 10

347 A. J. Gillespie, Glasgow. Improvements in rendering wickerwork baskets, hampers, or similar articles waterproof. January 10

367 J. Jameson, London. Improvements in the preparation of safety paper, affording protection against erasure or other alteration. January 10

368 F. B. Worsley Roberts, London. Improvements in the manufacture of gunpowder and analogous explosives. Communicated by F. Becker, Hamburg. January 10

382 W. Farnell and J. Simpson, Liverpool. Improvements in the utilisation of alkali waste from the Leblanc process in the manufacture of carbonate of soda, with production of sulphuretted hydrogen. January 12

400 A. Andrew, London. Improvements in mouthpieces and dies to be used in the manufacture of clay bricks, earthen pipes, and the like. January 12

408 T. Cobley, London. Improvements in the production of tanning and dyeing materials. January 12

419 F. Leslie and J. A. Wanklyn, London. Improvements relating to the preparation and use of coal gas, and in apparatus employed therefor. January 12

423 C. R. Schomburg, London. An improved mode of and apparatus for producing heat by the generation and combustion of hydrogen gas. January 12

440 L. Hill Armour, London. Improvements in writing ink. January 13

447 W. P. Thompson, Liverpool. Improvements in purifying vegetable fats and oils. Communicated by C. Helffrisch, Offenbach-on-the-Main. January 13

453 H. J. Worsum, London. A new or improved apparatus for reducing the heat of a body of water to an equal temperature throughout. January 13

463 S. Bowen Bowen, London. Improvements in apparatus for the concentration of sulphuric acid. January 13

471 W. Mather, London. A process for bleaching webs or yarns of vegetable textile materials. Complete specification. January 13

476 A. J. Boul, London. Improvements in the manufacture of felt, and especially for use in paper-makers' machinery. Communicated by A. Munzinger, Offen. January 13

479 J. Lietgetz y Sarda, London. Improvements in the manufacture or treatment of iron and steel. January 13

480 H. J. Wilberforce Raphael and J. Symb, London. Apparatus for disintegrating, crushing, or pulverising diamondiferous soil, gold quartz, and other minerals. January 13

491 W. Virgo Wilson and J. Storey, London. A new nitro-cellulose compound and products manufactured therewith. January 13

497 J. Robinson, Liverpool. Improvements in the treatment of spent oxides of iron and other substances containing sulphur, impure sulphur precipitate and impure melted sulphur, to obtain sulphur, and also arsenical compounds when the latter are present. January 11

500 F. B. Welch, Manchester. Improvements in the method of and apparatus for boiling sugar. January 11

510 J. Riley and W. Crossley, Glasgow. Improvements in and connections with furnaces for melting and treating iron, steel, ores, or other substances. November 8, 1881. Previously included in No. 11736, A.D. 1881.

529 S. Bennett, London. Improvements in the method of and apparatus for lifting, reining, and preserving beer. January 11

532 J. Maxim, London. Improvements relating to the manufacture of gunpowder, and to cartridges or charges containing or formed of the same. January 11

572 G. Asher, Birmingham. A new or improved method of annealing iron castings. January 15

629 H. Wagener and A. Mather, London. Improvements in purifying and utilising sewage and impure or waste waters. January 16

637 J. Atkinson, London. Improved apparatus for heating and purifying water for steam boilers and similar purposes. January 16

653 J. Duck, Glasgow. Improvements in apparatus for desiccating or drying air. January 16

658 E. Edwards, London. Improvements in the process of and apparatus for distilling alcoholic liquids by means of steam. Communicated by J. A. de Peyronny, France. Jan. 16

669 P. Walker, Glasgow. Improvements in making tiles and other articles with Portland or other cement. Complete specification. January 17

671 S. Trivick, London. Improvements in the treatment of certain ores containing silver, and the extraction of metals therefrom. January 17

687 Kasser, London. Improvements in the process of bleaching. Complete specification. January 17

690 J. F. Schnell and J. Read, Manchester. Improvements in obtaining gas for illuminating and other purposes. Jan. 17

693 C. D. Abel, London. Improvements in the production of sugar by the treatment of saccharine solutions with the alkaline earths. Communicated by M. M. Iotzen, Germany. January 17

731 T. Twynan, London. Improvements in the production of chlorine and hydrochloric acid from solutions of chloride of calcium. January 19

740 E. F. Trachsel, London. An improved method or process of purifying or separating calcium to obtain sulphur and other products. January 19

741 I. Lucas, London. A new or improved manufacture or production of albuminous matters. January 19

754 J. Stokes Williams, Riverton, New Jersey, U.S. Improvements in the methods of or means for operating metallic rolling mills, and utilising products therefrom, and in the methods and means employed therefor or therewith. Jan. 19

756 E. F. Trachsel, London. An improved method or process of decomposing bi-sulphide, hydro-sulphide, or sulph-hydrate of barium or of strontium to obtain sulphur and other products. January 19

757 E. F. Trachsel, London. An improved method or process of purifying hydrate of strontium. January 19

759 J. Sheldon Carter, and R. Hast Vigor, London. An improved composition for increasing the speed of steamers and sailing vessels, and preventing fouling generally. January 19

# ENGLISH PATENTS PUBLISHED.\*

APPLIED FOR DURING 1881.

491 B. P. Walker and J. A. B. Bennett. Self-acting retorts for the distillation of solid substances. 6d

Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reeder Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	1d.
Above 8d., and not exceeding 1s. 6d.	1d.
" 1s. 6d. " "	1d.
" 3s. 4d. " "	2d.

- 451 L. A. Groth. Communicated by R. Gratzel. Process and apparatus for the extraction of metals from their alkaline combinations. 6d.
- 1609 G. Valentine. Retorts for the production and revivification of animal charcoal from bones. 8d.
- 4752 A. Shippy. Collecting carbonated hydrogen, etc. 4d.
- 1813 J. C. W. Stanley. Treating certain deposits for the purpose of recovering nitrogenous matters therefrom. 2d.
- 1857 F. Wirth. Communicated by L. Starck. Preparing and using tanning substances. 2d.
- 1890 J. Harrison. The production and use of carbonic acid for refrigerating and aerating. 6d.
- 2020 G. T. Harrop. Compressing and expanding air for refrigerative purposes, etc. 6d.
- 2229 F. Weck. Machinery and apparatus for washing and scrubbing coal gas. 6d.
- 2133 B. L. Walker and J. A. B. Bennett. Distillation of solid substances. 6d.
- 2709 B. C. Sykes and J. Briggs. Apparatus for making producer gas, heating water, and generating steam. 8d.
- 2716 E. Webers. Casting steel, iron, etc. 6d.
- 3083 P. A. Maiguen. Compound for the elimination of dissolved matter from water. 4d.
- 3090 G. Morris and G. Slater. Puddling furnaces. 6d.
- 3174 A. Myall. Communicated by Chailly. Tanning hides and skins. 6d.
- 3236 H. Hack and F. Ley. Apparatus for receiving and conveying away coke drawn from gas retorts or coke ovens, and for delivering the same into wagons, etc. 8d.
- 3323 F. Wirth. Communicated by H. Herberts. Method of and apparatus for treating acid sulphate of soda or bisulphate of soda for industrial purposes. 6d.
- 3152 H. H. Lake. Communicated by P. A. Mallet and T. A. Pagniez. Apparatus for distilling liquids for purifying gas, etc. 6d.
- 3320 J. G. Williams. Carbonising coal. 4d.
- 3536 F. M. Lyte. Protecting submerged structures of iron and steel from corrosion and fouling. 4d.
- 3615 R. Baynes and A. Bigland. Treating, refining, or bleaching cotton seed and other oils. 2d.
- 3636 J. B. Elliott. Treating liquid or other materials to concentrate and dry the same, and apparatus therefor. 6d.
- 3726 W. A. Byrom and J. A. B. Bennett. Method of taking off the volatile products from coal, shale, and other hydrocarbons during the process of distillation. 6d.
- 3730 L. M. Dufus. Communicated by J. Ponty. Preparation of noninflammable pulp for the manufacture of paper, and for other purposes. 4d.
- 3736 L. M. Dufus. Communicated by J. Ponty. Means for rendering objects incombustible. 2d.
- 3750 H. W. Koenig. Treatment of fibrous materials for the preservation thereof. 6d.
- 3870 J. F. Belfield. Washing and purifying coal gas. 6d.
- 3921 W. F. Baths. Basic linings for open hearth steel and iron furnaces. 6d.
- 3939 L. D. York. Producing gas for heating purposes. 6d.
- 3987 W. T. Walker. Condensing apparatus for purifying coal gas. 6d.
- 3996 F. Groom Redman and J. Bunt. Making sewage refuse into artificial manure. 4d.
- 4102 S. Pitt. Communicated by H. Pemberton, Philadelphia. Manufacture of bichromate of potassa and other chromates. 4d.
- 4191 J. C. Morrill. Treatment of domestic refuse for sanitary purposes, etc. 6d.
- 4268 S. G. Thomas. Manufacture of alkalis and alkaline salts. 2d.
- 4304 A. M. Clark. Apparatus for agitating the liquid in liming vats. Communicated by J. B. McEnally. 6d.
- 4333 J. Miles. Method of extracting metals from the material found combined with coal, commonly known as iron stone. 4d.
- 4117 W. S. Richardson and W. J. Grey. Treatment of chloride of sodium for the production of bleaching-powder, and other materials therefrom. 6d.
- 4452 G. C. Denison and J. E. Higgins. The manufacture of salt from brine, and apparatus therefor. 6d.
- 4480 W. L. Wisc. Communicated by C. H. Knoop. Manufacture of mordants and colouring matters from glucosides, tannin, and bitter principles. 4d.
- 4529 F. Nowlan. Safety paper for cheques, etc. 6d.
- 4707 J. B. Thompson. Improvements in bleaching. 2d.
- 4718 W. Black and T. Larkin. Furnaces for the manufacture of sulphate of soda or hydrochloric acid, or for roasting or calcining ores, etc. 6d.
- 4792 A. Snowball. Composition or compound for covering boilers, pipes, ice safes, etc. 2d.
- 4796 P. Leyden and W. McLcan. Priming and anti-fouling compositions. 4d.
- 4826 W. J. Gale. Treating leather for the purpose of rendering the same water-repellant, water-proof and more durable. 2d.
- 5151 J. Inray. Communicated by H. J. E. Hennebatte. Manufacture of resin soap. 2d.
- 5221 J. L. Riley, J. Downham, and J. Apsley. Mode of bleaching linen and jute in the fibres, yarn, and in the woven material manufactured therefrom; and apparatus used therein. 6d.
5257. H. Walley and T. Gare. Protecting from damp, moisture, or decay; and in varnishing and enamelling; and in some cases hardening or toughening stone, brick, tile, earthenware, etc. 4d.
- 5358 A. Prinz and E. Quellmalz. Treatment of vegetable fibres, etc. 4d.
- 5381 G. W. von Nawrocki. Communicated by Wellstein. Extracting fat and gine from bones. 6d.
- 6155 E. A. Bridges. Communicated by W. F. C. M. McCarty. Process of manufacturing hydrocarbon gas and apparatus therefor. 6d.
- 6200 H. Seney. Malting the grain used in the fabrication of beer. 6d.
- 6573 P. W. Renault. A ferment for use in indigo vats, and in vats for dyeing with noir bleu or with mixtures of noir bleu and indigo. Communicated by C. Collin and L. Benoist. 4d.
- 6574 P. W. Renault. Communicated by C. Collin and L. Benoist. Improvements in indigo vats and in vats for dyeing with noir bleu or with mixtures of noir bleu and indigo. 4d.
- 6882 A. M. Clark. Communicated by W. Maynard. Apparatus for purifying and hydrating gases. 6d.
- 7080 R. McNichol and J. Walsh. Mixing or disintegrating fluid and semi-fluid substances. 4d.
- 8118 P. Kempf. Process of manufacturing iodoform, bromoform, and chloroform. 2d.
- 8218 T. Kempf. Process of manufacturing permanganates. 2d.
- 8890 J. H. Loder. Process for preparing aromatic colouring matters by the action of a saccharine solution in a state of alcoholic fermentation upon other aromatic compounds. 4d.
- 9084 A. J. Boulton. Communicated by J. Hanlon. Manufacture of illuminating or heating gas, and apparatus therefor. 6d.
- 9305 W. Weldon. Improvements in and relating to the manufacture of chlorine. Communicated by A. R. Pechiney et Cie. 6d.
- 9495 A. M. Clark. Communicated by J. Garnier. Method and furnace for obtaining crude copper directly from copper ores and mattes. 6d.
- 12513 S. Puppelt. Apparatus for compressing the condensable gases. 6d.
- 12912 J. H. Hislop. Retorts for obtaining from coal or other carbonaceous substances illuminating or heating gas, oil, coke, and other products. 6d.
- 12325 T. H. Johns and W. A. Johns. Improved method of tinning plates. 6d.
- 13343 W. R. Lake. Communicated by S. Wheeler. Manufacture of medicated paper, and apparatus therefor. 6d.
- 13390 P. Jensen. Communicated by A. Vogt and A. Figue. The production of alkali carbonates, and apparatus therefor. 6d.
- 11011 J. Inray. Communicated by L. Cuisinier. Process for extracting and saccharifying ingredients of amylaceous substances by treatment with malt. 6d.
- 1241 A. M. Clark. Communicated by A. Denom. An improved composition mastic. 2d.
- 11361 M. Cock. An improved coating for explosive compounds and cartridges. 2d.
- 11770 G. E. Ellis. Manufacture of filtering, disinfecting, decolorising, and colouring medium. 2d.
- 11852 A. W. L. Reddie. Communicated by J. J. Crooke and R. Crooke. Improvements in treating copper matte. 4d.
- 11892 J. A. Elliott. Communicated by E. Fitch. Apparatus for sulphurising and phosphorising friction matches. 6d.
- 15110 C. Scheebler. Improvements in the treatment of phosphatic slags. 2d.

## SECOND EDITIONS AND REPRINTS.

- 13081 A.D. 1850. W. Radley and F. Meyer. Treating fatty and other bodies. 1s. 6d.
- 840 A.D. 1863. B. Latham. Filtering and straining sewage. 8d.
- 1376 A.D. 1872. J. G. Fitzgerald and B. C. Molloy. Treating compound substances by electricity. 6d.
- 1192 A.D. 1872. T. Christy and A. Bobrownicki. Treating ammoniacal liquors. 6d.
- 5061 A.D. 1876. C. and A. Forrest. Drying and powdering blood. 6d.
- 5367 A.D. 1882. J. A. Graham. Coating iron with lead. 4d.

# THE JOURNAL OF THE Society of Chemical Industry:

## A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 2.—VOL. IV.

FEBRUARY 28, 1885.

Non-Members 30s. per annum; Members  
21s. per Set; Single Copies 2s.

### COUNCIL.

*President:* Dr. W. H. Perkin, F.R.S.

*Vice-Presidents who have filled the Office of President:*

Sir H. E. Roscoe, Ph.D., LL.D., F.R.S.  
Sir Frederick Abel, C.B., D.C.L., F.R.S.  
Walter Weldon, F.R.S.

*Vice-Presidents:*

Alexander M. Chance.  
George E. Davis.  
Prof. James Dewar, F.R.S.  
James Duncan.  
David Gamble.  
David Howard.  
D. B. Hewitt, M.D.  
E. K. Muspratt.  
J. C. Stevenson, M.P.

*Ordinary Members of the Council:*

Eustace Carey.  
Prof. Chas. Graham, D.Sc.  
Peter Griess, Ph.D., F.R.S.  
Ivan Levinstein.  
R. Messel, Ph.D.  
B. E. R. Newlands.  
John Pattinson.  
Thomas Lloyd.  
John Spiller.  
Prof. W. A. Tilden, F.R.S.  
John Williams.  
P. J. Worsley.

With the Chairmen and Secretaries of Local Sections.

*Honorary Treasurer:*

E. Rider Cook, East London Soapworks, Bow, E.

*Honorary Foreign Secretary:*

Ludwig Mond, 28, Park Crescent, Portland Place, W.

*General Secretary:*

Charles G. Cresswell, Palace Chambers, 9, Bridge Street,  
Westminster.

### THE JOURNAL.

*Publication Committee:*

*The President.*

Sir F. A. Abel, F.R.S.  
Joseph Bernays, M.I.C.E.  
Eustace Carey.  
W. Lant Carpenter.  
George E. Davis.  
Prof. Dewar, F.R.S.  
Chas. Ekin.  
Prof. Chas. Graham, D.Sc.  
Peter Griess, Ph.D., F.R.S.  
D. B. Hewitt, M.D.  
David Howard.  
Prof. A. K. Huntington.  
F. Hunter, Ph.D.  
E. W. T. Jones.

Ivan Levinstein.  
Raphael Meldola.  
Ludwig Mond.  
Chas. O'Neill.  
C. O'Sullivan.  
John Pattinson.  
Sir H. E. Roscoe, F.R.S.  
Prof. C. Schorlemmer,  
F.R.S.  
John Spiller.  
A. Norman Tate.  
Thomas Tyrer.  
Walter Weldon, F.R.S.

*Editor:* Watson Smith, The Owens College, Manchester.

ASSISTED BY THE FOLLOWING STAFF OF

*Abstractors:*

H. Baker.  
G. H. Beckett.  
D. Bendix.  
E. J. Bevan.  
W. Dalrymple Borland.  
C. F. Claus, Ph.D.  
E. G. Clayton.  
Julius B. Cohen, Ph.D.  
C. F. Cross.

### NOTICES.

Authors of papers printed in the Journal are hereby notified of the fact that, in accordance with Bye-law 43, they are entitled to receive not more than 50 gratuitous copies of their papers. Authors should state on their manuscripts their desire to have free copies, adding the number wished for. Unless the contrary be specially desired, this being stated on the manuscript, the reprints of an author's paper will not include the report of any discussion that may have arisen after the reading of the paper.

Members are hereby advised that the Subscription for 1885 falls due at the beginning of the year, and should be paid as soon afterwards as possible. The Council has decided that after January 1st, 1885, the 29th Bye-law will be strictly enforced, so that Members whose subscriptions are more than four months in arrear, will not continue to receive the Society's Journal.

Inquiries having been made as to the transactions of the Newcastle Chemical Society, the Committee of the Newcastle Section have to state that a very few complete sets are remaining, and will be sold to members at £2 10s. per set. A number of separate volumes can also be had by members wishing to complete their sets, at 10s. per volume (generally three years' issue). Application for these should be made to the Local Secretary of the Newcastle Section.

### LIST OF MEMBERS ELECTED FEBRUARY 23rd, 1885.

F. T. Addymann, 17, Tennyson Street, Nottingham, science student.  
Hy. Ashwell, Woodthorpe Grange, Sherwood, Nottingham, bleacher, etc.  
J. H. Ashwell, Woodthorpe Grange, Sherwood, Nottingham, bleacher and dyer.  
Capt. J. E. Bowly, R.N., Elm House, Trinity Road, Birchfield, Birmingham, brewer.  
Wm. Bramley, 18, Clarence Street, Middlesbro'-on-Tees, chemist.  
Alex. Buchan, 13, Willowbank Crescent, Glasgow, technical chemist.  
W. H. Carey, Forest Works, Bulwell, near Nottingham, laec bleacher.  
Arthur Clarke, St. Ann's Hill Factory, Nottingham, bleacher and dyer.  
Jos. H. Coleman, University College, Nottingham, demonstrator of chemistry.  
Claude H. Cooper, The Towers, Old Sneinton, Nottingham, hosiery manufacturer.  
S. Corner, B.A., 95, Forest Road West, Nottingham, schoolmaster.  
H. W. Cuthbert, 88, Bishopsgate Street Within, London, E.C., Russia broker.  
R. M. Cuthbert, 27a, Ashley Place, London, S.W., Russia broker.  
Geo. D. Davis, 219, High Holborn, London, W.C., bleacher.  
Wm. Dawson, Clingford Hall, Leyton, E., civil engineer.  
H. Doidge, 19, Alberta Terrace, Sherwood Rise, Nottingham.  
Edmund Dowling, 83, Cable Street, London, E., oil merchant.  
Chas. A. Drake, Three Mills Distillery, Bromley by Bow, E., brewer.  
E. W. Field, The Brewery, Nottingham, brewer.

S. E. Field, The Brewery, Nottingham, brewer.  
 R. Kitchin, 21, Long Row, Nottingham, pharmacist.  
 Louis Gatin, 25, Rue des Rosiers, Paris, chemical manufacturer.  
 James Gow, High School, Nottingham, Fellow of Trinity College, Cambridge.  
 J. Albert Hall, 9, Mary Street, Harpurhey, Manchester, science student.  
 Oswald Hamilton, Owens College, Manchester, chemist.  
 S. V. Hoigate, 29, Long Row, Nottingham, pharmacist.  
 W. Freeman Horn, Grove Works, Lombard Road, Battersea, S.W., white lead manufacturer.  
 F. C. Humphreys, Gas Works, Ilkeston, Nottingham, gas engineer.  
 S. D. Leah, 554, London Road, Nottingham supervisor, Inland Revenue.  
 Oliver M. Lilly, The Croft, Spondon, Derby, colour manufacturer.  
 H. Martin, Poole, near Wellington, Somerset, manager, manure works.  
 Thomas McGill, Tar and Liquor Works, Beeton, E., chemist.  
 Daniel Mesad, The Patent Office, Chancery Lane, W.C., examiner.  
 E. T. Mays, 131, St. Vincent Street, Glasgow, civil and mining engineer.  
 Thos. Morgans, The Guildhall, Bristol, civil and mining engineer.  
 S. J. Pentecost, Regent Street, New Basford, Nottingham, lace dresser.  
 E. T. Purser, 82, James Street, Dublin, brewer.  
 T. N. Risdon, 93, St. Saviours Road, Jersey, gas engineer.  
 W. Shackel, Three Mills Distillery, Bromley by Bow, E., brewer.  
 A. H. Simpson, University College, Nottingham, demonstrator of physics.  
 Arnold Spiller, 2, St. Mary's Road, Canonbury, N., chemist.  
 H. J. Staples, Spondon, Derby, colour manufacturer.  
 H. Suillot, 21, Rue St. Croix de la Bretonnerie, Paris, chemical manufacturer.  
 C. Taylor, Friars Field Villas, Uttoxeter New Road, Derby, M.D.C.E.  
 Edgar H. Truman, 31, Derby Road, Nottingham, M.D., borough analyst.  
 T. F. P. Bruce Warren, Tamworth Villa, Earllam Grove, Forest Gate, E., chemist.  
 John F. Warwick, The Brewery, Newark-upon-Trent, brewer.  
 Ernest Weldon, 86, North Gate, New Basford, Nottingham, dyer.  
 Osmond Weldon, 66, North Gate, New Basford, Nottingham, dyer.  
 C. J. Whittaker, 75, Plantation Street, Accrington, chemical engineer.  
 Walter H. Wilkin, Appold Street, Finsbury, E.C., yeast manufacturer.  
 A. R. Wright, Patent Office, 25, Southampton Buildings, W.C., civil service.  
 Jos. Wright, 19, Arboretum Street, Nottingham, lace dresser.  
 Brougham Young, Home Lgn, Woodberry Down, London, N., chemical student.  
 Armourer Hedley, Mayfield, Gosforth, Newcastle-on-Tyne, soap manufacturer.

#### CHANGES OF ADDRESS.

E. E. Berry 40 o Bristol, 27, Upper Bedford Place, London, W.C.  
 Jas. T. Brown d o Edith Grove, 14, Margaretta Terrace, Oakley Street, Chelsea, S.W.  
 Wm. Douglas d o Glasgow, Diamond Plantation, Demerara.  
 U. K. Dutt d o St. Mary's Hospital, 70, Portlands Road, Maiden Vale, N.W.  
 H. B. Fulton d o Quebrada Copper Co., Kirkintilloch, near Glasgow.  
 L. Goldenberg d o London, Edison Machine Works, 107, Gerrard Street, New York, U.S.A.  
 A. J. Greenaway d o Upper Holloway, Frognaal, Hampstead, N.W.  
 G. G. Henderson, address all communications to Chemical Laboratory, University of Glasgow.  
 Jas. Higgins d o Kersb, The Hollies, Timperley, Cheshire.  
 J. W. Jones d o Dinting, Oakwood, Swinton Park, Manchester.  
 Jas. Keen d o 37, 3, Croft Terrace, Jarroon-Tyne.  
 A. S. Lodge d o Prestwich, c o J. H. Gartside & Co., Ltd., Maccanay, Eton, France.  
 Jas. Macleod d o Glasgow, c o L. Sterne & Co., 10, Victoria Chambers, Westminster, S.W.  
 E. V. Miller d o Liverpool, c o The New Zealand Sugar Co., Auckland, New Zealand.  
 J. Napier d o Bramford, 1, St. Matthew's Place, Norwich Road, Ipswich.  
 Ralph W. Robinson d o Widnes, The Great Hall Street, Tunbridge Wells.  
 F. Rohling d o Oldham, c o Messrs. Rohling and Rave, Munster, Westphalia, Germany.  
 A. Sanson d o Old Trafford, 5, Tivoli Place, George Street, City Road, Manchester.  
 H. E. Schofield d o Manchester, 52, Edge Lane, Liverpool.  
 H. Shepherd d o Dublin, 2, Orlando Road, Clapham, S.W.  
 Dr. Karl F. Stahl d o Nashville, Johnston Chemical Works, Johnston, Cambria Co., Pa., U.S.A.

F. Tennant (d o Gateshead-on-Tyne), 195, West George Street, Glasgow.  
 G. C. Trewby d o Beckton, The Gas Light and Coke Co., Horseferry Road, Westminster, S.W.  
 A. W. Warrington (d o Liverpool), 2, Ruprechtsauer Allee, Strassburg, Elsass.  
 Wm. Windus (d o Beaconsfield Road), 1, Hughenden Road, Clifton, Bristol.

#### MEMBER RESTORED ON PAYMENT OF SUBSCRIPTION.

Jos. Singleton, 11, Corporation Street, Manchester.

#### Deaths.

J. B. Lindsay, 1 o Chemical Works, Irvine, N.B.  
 S. Gilchrist Thomas, 1 o Palace Chambers, Westminster, S.W.

#### London Section.

#### CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: David Howard.

#### Committee:

Sir F. A. Abel.	B. E. R. Newlands.
H. E. Armstrong.	B. Richwood.
W. Crowder.	T. Royle.
C. Graham.	John Spiller.
S. Hall.	G. C. Trewby.
A. K. Huntington.	W. Weldon.
R. Messel.	J. Williams.

Local Sec. and Treasurer: Thos. Tyrer.  
 Garden Wharf, Church Road, Battersea, S.W.

MEETINGS, SESSION 1885—First Monday in each month (unless otherwise indicated).

March 2.—(1) Mr. W. J. Kemp—"Some Experiments upon that part of Mr. F. B. Rawes's Patent for the 'Recovery of Sulphur,' etc., which depends upon the Action of Carbon Dioxide upon Soda Waste Suspended in a Liquid."  
 (2) Mr. W. J. Williams—"The Treatment of Certain Phosphatic Minerals."

(3) "The Staff-Test Salt Industry, and its bearing on other Industries," by C. Napier Lake and Charles Mook.  
 April 13.—(Monday after Easter)—Mr. W. J. Dibdin—"Further Notes on the 'Radial Photometer, and the Proposed Standards of Light.'"

Notices of papers and communications for the meetings to be sent to the Local Secretary.

Meeting held February 2, 1885.

#### THE RUSSIAN PETROLEUM INDUSTRY.

BY BOVERTON REDWOOD, F.L.C., F.C.S.

SHORTLY after my return from a visit to Baku and the principal distributing centres of the petroleum trade in Russia, last autumn, it was suggested to me that some account of the Caucasian petroleum trade would be of interest to the members of the Society of Chemical Industry. Much has been already published on the subject; but it appeared to me, upon consideration, that the whole ground had not been covered, and that the members of this society might justifiably be addressed on the technical and commercial aspects of the question.

I propose to divide my remarks under three heads—viz., (I.) Production (as the obtaining of the crude petroleum is termed), (II.) Refining, and (III.) Distribution. Under the second head I shall deal with the properties and uses of the various products, and shall bring the third section to a conclusion with a very few words in reference to the routes to Baku, in the hope that some of those present to-night may be induced to make the trip. The majority of the statistics I shall give are from notes taken during my journey; but some are quoted from the valuable official reports of Mr. Peacock, H. M. Vice-Consul at Batoum, and

from Mr. Charles Marvin's publications. I am indebted to Mr. Ludvig Nobel, as well as to Mr. Crusell, Mr. Ryden and many other officials of the Nobel Company, particularly Dr. Lagerwall, the courteous Secretary of the Company, for replies to many questions, and for affording me special opportunities of making myself acquainted with the industry. I have also to thank Mr. Burkhardt of Batoum, Mr. D. N. Sackel, agent in London for Mr. S. E. Palaschowsky and the Batoum Naphtha Industry and Commerce Company, and Mr. E. G. von Glehn, representative of the Ragosine Company, for much valuable information.

### I.—PRODUCTION.

Anyone whose experience of oil-producing territory has been gained in the United States, cannot fail to be impressed, on first visiting the neighbourhood of Baku, with the very limited extent of the area within which, practically the whole of the crude oil is being collected. The oil-field from which the Baku refiners are supplied, is not in fact more than  $2\frac{1}{2}$  miles square; and on this small tract of land there are flowing wells or fountains which apparently could supply the whole world with lamp oil and lubricating oil. It must not, however, be assumed that the oil-bearing lands of Russia are of small area. On the contrary, it has been estimated that petroleum deposits underlie no less than 14,000 square miles, and admitting that this estimate is not based upon very reliable data, there is, I believe, no reason to doubt that something like 1000 or 1200 square miles of the Apsheron peninsula may be fairly regarded as more or less productive oil territory. No systematised attempts have yet been made to explore this large field, and strictly define its limits, for the reason that more than sufficient oil is obtained within the narrow limits I have referred to.

The locality of the existing wells is termed the Balakhani or Balakhani-Sabontchi district, and it is distant about eight miles from the town of Baku, at an elevation of something less than 200 feet above sea level. A few miles away, at Surakhani, is another group of wells on the site of the prehistoric Sacred Fires; but these wells are of minor importance. Petroleum has also been obtained in quantity at Konban, about 60 miles inland from Novorossisk, on the shores of the Black Sea; and evidence of the extension of the oil-field in a north-westerly direction has been furnished by the result of trial borings in the Crimea. In the neighbourhood of Tiflis, and in a large number of other places throughout the Apsheron peninsula, there are also petroleum pits and natural outflows of petroleum, some of which have been locally utilised. While, as I have said, the petroleum field appears to extend into the Crimea (though it is possible that there may be a succession of deposits rather than an actual belt), there is evidence of its continuous extension from Baku across the Caspian Sea to the Trans-Caspian territory. Near the Baku coast the surface of the sea is frequently covered with oil, which has floated to the surface; and in still weather the petroleum gas may be ignited. The island of Tchelleken, immediately opposite, and distant about 200 miles, contains apparently immense deposits of ozokerite. I hoped to have been able to visit this interesting place, but the Russian Government has, for political reasons, prohibited Englishmen from landing there; and in Russia the rigid passport-registration system makes every movement of the traveller known to the authorities. On the mainland, in the Trans-Caspian territory, there is stated to be abundance of petroleum; but except to supply fuel for the railway this source is not utilised.

The existence of the petroleum deposits of Baku

has probably been known for 2500 years, for it is believed that the Persian fire-worshippers frequented Surakhani from the time of Zoroaster, who lived not later than 600 B.C. Gibbon states that in A.D. 624, the Emperor Heraclius wintered at the mouth of the river Kura, 70 miles south of Baku, and that his "soldiers extinguished the fire and destroyed the temples of the magi." Marco Polo, who wrote in the thirteenth century, is supposed to have referred to the petroleum of Baku when he stated that there was in this neighbourhood an abundant spring of oil not good for food, but good to burn, or to anoint camels that had the mange; and he added that people came from great distances to fetch it. In Jonas Hanway's time (the middle of the eighteenth century), Indians were worshipping at the Surakhani temple, as many as 50 pilgrims congregating there at one time. Hanway described the eternal fire as a flame in colour and gentleness not unlike a lamp that burns with spirit, only more pure, and sometimes rising to a height of eight feet, when the wind blows. I have on the table a photograph of this temple as I recently saw it. In the centre of a walled quadrangle stands a solidly built pillared and roofed rostrum of white stone, surmounted by a small trident. Around the boundary walls, with entrances from the quadrangle, are stone cells, which bear evidence of having been used as dwellings. Within these cells, and in the courtyard, there are many fissures in the ground, and upon applying a lighted match to some of these, I had no difficulty in igniting the gas, which burned with a flame of so little luminosity that in the bright daylight it was difficult to trace its outline. In some places channels of stone had been constructed to convey the gas. At the time of my visit there were neither officiating priests nor devotees, but a bell that had been used to summon the faithful, still remained suspended. Returning to the historical aspect of the subject, as to which I have only a very few more words to say, I may mention that Tchelleken island was referred to by Hanway, under the name of Naphtonia or Cherriken, as being peopled, when he visited it in 1743, by about 26 families, who had 24 large boats, owned several wells of naphtha, and carried on a brisk trade in selling the oil to Persians, Turcomans, etc. Colonel Yule states that the quantity of naphtha collected from the springs about Baku was, in 1819, estimated at 241,600 poods (more than one million gallons), the greater part of which went to Persia. Crude petroleum is still burned as a source of light in some parts of Russia, in earthenware lamps of primitive form, one of which I have on the table.

Very little is known concerning the geology of the Southern Russian oil-fields; and experience gained in petroleum-well boring in the United States, does not appear to be of much value in the Apsheron peninsula. Instead of the oil being found, as it is in America, in well-defined strata of sand-rock, it appears to exist in the Caucasus for the most part in separate cells or pockets. Professor Abich says the rocks can be assigned to the miocene formation, of which there are traces of two layers, above these being tertiary clays and sands; but the whole region has evidently been affected by volcanic action, and the strata have been broken up. Not far from Baku is an extinct mud volcano, from the sides of which petroleum exudes. The limestone found in the neighbourhood, much of which is so soft that it is squared for building with axes, is full of shells of molluscs; and this particular stone and petroleum seem to go together in the Caucasus. I remember, when visiting the Bradford oil-field in the United States, having a somewhat similar stone (a specimen of which is on the table) pointed out to me as a surface indication of petroleum. I do not propose to say much on the present occasion in

reference to the various theories put forward as to the origin of petroleum. It is well known that while some are disposed to consider petroleum as a product of the destructive distillation of coal, many more look upon it as derived from the remains of marine animals. In addition, we have Professor Mendelejeff's ingenious theory that petroleum results from the action of water at a high temperature, and under great pressure, upon compounds of iron, manganese and carbon; and I would refer those who are interested in the question to this distinguished chemist's essay, entitled—*"L'Origine du Pétrole,"* published in the *Revue Scientifique*, of November 3, 1877.

The peninsula of Apsheron projects in an easterly direction from the mainland of Trans-Caucasia, and upon the southern shore of the bay thus formed lies the town of Baku. The northern side of this peninsula is tolerably fertile; but the neighbourhood of Baku presents the appearance of a desert of sand and rock, here and there stained black by the exudation of petroleum, and with occasional deposits of salt glittering in the sun. The only vegetation which thrives in this district is the prickly camel-thorn; and it may be imagined that a more dreary prospect is nowhere presented to the eye. The oriental-looking Tartar villages, with solid flat-roofed stone buildings, surmounted by the characteristic domed chimneys, form inconspicuous features in the landscape, hardly distinguishable at a distance from the surrounding desert; and at intervals along the so-called roads water wells of primitive form are met with. Strings of camels, bearing skins of petroleum to Daghestan villages; tall sheep-skin-hatted Tartars riding on small donkeys, and gaudily-painted Persian "arbas," or two-wheeled carts, to which I must again refer, add to the thoroughly Eastern character of the scene.

The contrast between this silent desert and the bustle and confusion of the oil wells is most marked. Within the area of the present producing territory derricks are crowded together, a network of pipes like so many gigantic serpents covers the oil-sodden ground, miniature mountains of sand thrown up by the spouting wells abound, and all the remaining space is occupied by lakes of crude oil, as well as storage tanks for its reception before it is pumped to the refineries.

I had seen wells in America that were considered remarkable in regard to the quantity of oil yielded, and had read accounts of the productiveness of the Russian wells, but I was, I must confess, wholly unprepared for the evidence of abundant supply afforded by the flowing wells, or fountains, as they are locally termed, which have been struck in the Balakhani district. These wells are invariably capped to prevent waste and damage to neighbouring wells, as I shall presently explain. One of the fountains was opened in my presence, and immediately with a roar a mighty column of oil more than a foot in diameter shot up to a height exceeding 100 feet, and continued to flow without diminution of violence as long as the valve remained open, forming a lake of oil to leeward of the well. The derrick over the well was 70 feet in height, and the oil column occasionally rose to at least double this height, while stones were distinctly seen to be projected to an even greater altitude. An American who was with me said he could compare the spectacle with nothing but the falls of Niagara, and there was certainly the same awe-inspiring effect in watching nature disgorging her treasure that one experiences when standing on the brink of the stupendous Falls. The photograph exhibited (see Fig. 1) represents a Caucasian oil fountain. The well I saw spouting (Nobel's No. 18) yields at the rate of 1,125,000 gallons per 24 hours whenever opened, and

is by no means the most productive that has been struck, the Derojba well and Nobel's No. 9 well having for a time yielded about double that quantity per 24 hours. In the case of these two wells the pressure of the oil amounted to about 200lb. on the square inch, and the oil column was from 200 to 300 feet in height. In the instance of Nobel's No. 9 well no great proportion of the oil was lost before the well was capped, but the Derojba fountain was for no less than four months quite uncontrollable, and it is estimated that from 68,000,000 to 136,000,000 gallons were ejected during this period. This quantity of American crude oil was worth in the United States at the time from £700,000 to £1,400,000 sterling, but in consequence of the impossibility of storing it, the oil spouted by the Derojba well was practically unsaleable. Not only was the greater part of the oil lost, but great damage was done to surrounding well property, engine houses being buried by the sand thrown up. It may afford a means of realising the enormous productiveness of these wells, if I state that the well known as Armstrong No. 2 struck last

FIG. 1.

autumn in Butler county, Pennsylvania, flowed for a time at the rate of 260,000 gallons per 24 hours, and is considered one of the most prolific wells ever known in the oil regions of the United States. The yield of this well, it will be noted, is only about one-eighth of that of the Derojba well or of Nobel's No. 9 well.

The first step in the operation of boring a well is the erection of a derrick. I have on the lecture table a model made for me in the United States which illustrates the method of construction, derricks of the same form being used in Russia. It will be seen that the structure consists of a timber framework, pyramidal in form and strengthened with diagonal braces. The sides of the derrick are frequently, I may say usually, enclosed with boarding to a considerable distance from the ground, to keep out wind and rain. The height of the structure is commonly about 70 feet, and it is about 20 feet square at the base. Immediately outside the derrick stands what is termed in America the Sampson-post, a massive pillar of wood some 18 inches square, which supports the "walking beam." The walking beam is connected to the crank of the band-wheel by what is called a pitman, and a rocking movement is thus imparted to it

by the steam engine in the adjoining shed. There are two methods of boring in use in the Caucasus, termed respectively the rod system and the rope system, the latter being the more expeditious, and admitting of from 7 feet to 8 feet being bored per working day of 10 hours. In the rod system of boring the bit is screwed into an iron rod which may be as much as 40 feet in length, and a vertical movement is imparted to the apparatus by the walking beam already alluded to. As the hole increases in depth, additional lengths of iron rod are added, in the same way that the chimney sweeper manipulates his machine. At frequent intervals, however, it becomes necessary to remove the detritus from the bore, and when the well has been sunk to a considerable depth (say 200 to 300 feet), the time occupied in unscrewing each rod as the drill is drawn up, and reconnecting the rods after removing the detritus, is considerable. In the rope system, the set of drilling tools, consisting of temper screw, rope socket, auger-stem, the jars, and bit, are suspended by a stout cable of manilla. The aggregate length of this set of tools is over 50 feet, and the weight about a ton. The bits used in America are about  $5\frac{1}{2}$  inches in diameter, and are faced with about 40 pounds of steel, but in Baku the wells are of greater diameter and the bits correspondingly larger. As the boring of the well progresses it is eased with iron tubing, which is lowered in successive lengths. Tubing as much as  $16\frac{1}{2}$  inches in diameter is occasionally used in Russia, but the usual size with which the casing of the well is commenced is 15 inches diameter, the tubing being added in successive lengths of 7 feet. As the depth of the well increases and the larger tubing can no longer be driven down, smaller tubing is used, and the lower lengths are sometimes less than 8 inches in diameter. I have already stated that from time to time the detritus has to be removed. For this purpose the drilling tools are drawn up through the medium of the strong windlass (technically known as the bull-wheel) fixed to the side of the derrick, and actuated by the same steam engine that moves the walking beam, and then a few bucketsful of water having been poured into the well, the "sand pump" is lowered by means of a small windlass. This sand pump consists of a tube or cylinder of metal some 6 feet or more in length, having at the lower end a valve opening inwards. The detritus having entered the tube through the opening of the valve, the tube is withdrawn with its contents, and this operation is repeated as many times as are necessary. The cost of sinking a well is about £2000, more or less, according to circumstances, the irregular character of the strata rendering the operation more difficult and costly than it is in the United States. As soon as oil is struck, the great anxiety is to affix a cap to the upper end of the well tubing before the flow becomes unmanageable. A difficulty arises from the fact that the oil contains a great deal of sand, the violent flow of this sand-laden oil quickly cutting through a considerable thickness of iron. I saw in Balakhani several caps which had thus been rendered useless. The caps used are provided with a valve so that the flow may be controlled and regulated. In many cases it is found necessary to artificially strengthen the ground surrounding the well, in order to prevent the oil from making its way to the surface outside the tube when the flow is checked, and in the case of some wells the closing of the valve is attended with the risk of the cap being blown off by the immense pressure of the oil. It has more than once happened that on the oil being struck the outflow has taken place with such violence that the drilling tools, weighing as I have said a ton, have been projected from the bore. The employment of nitro-glycerine for increasing the

production of a well, so common in the United States, has not, I believe, hitherto been resorted to in the Caucasus.

It is stated that there are over 400 wells in the neighbourhood of Baku (as compared with more than 20,000 in the oil-fields of the United States), but of these I was informed that only about 100 were at the time of my visit producing. Rather more than half the producing wells are owned by the firm of Nobel Brothers. Of the 100 wells only some 20 are flowing wells, the remainder requiring to be pumped; but from what I have stated as to the productiveness of the fountains, it will readily be believed that if the oil were allowed to flow, these 20 wells would for a time yield far more than sufficient raw material for the manufacture of the 1,800,000 gallons of petroleum burning oil which the world is now daily consuming.

The oil containing too much sand to admit of ordinary pumping, it is lifted to the surface by a contrivance similar to that which I have described as being employed for removing the detritus during the sinking of the well. The valved tube thus used holds about 45 gallons, and it is stated that from 18,000 to 22,000 gallons can thus be raised from each well per working day of 10 hours.

The average depth of the wells last year was 450 feet, having been in 1873, 154 feet; in 1880, 273 feet; and in 1882, 350 feet. It is estimated that the average level of the oil is lowered to the extent of 56 feet for every 500 million gallons extracted.

The No. 18 well (Nobel Brothers), which I saw spouting, has a depth of 721 feet. The boring was at first stopped at 500 feet, but the flow having ceased, the well was deepened. This well was struck three years ago. The depth of the famous Dragoba well is 574 feet. I may add for comparison that 1500 feet or more is now by no means an uncommon depth for petroleum wells in the United States.

Soon after the annexation of Baku by Russia in 1801, the attention of the Russian Government was turned to the natural wealth of this district, and the production of petroleum was at first farmed out as a monopoly to Meerzoeff. This continued till 1872, and from then till 1877 there was an excise duty. During the period extending from 1821 to 1872 the yearly revenue from the petroleum monopoly was never far short of, and often exceeded, 100,000 roubles, and in the latter year it had reached the sum of 136,000 roubles. The output increased from 3565 tons in 1840 to 24,800 tons in 1872, but in two previous years—viz., 1869 and 1870—the output exceeded 27,000 tons. In 1872 there were only two drilled wells, in addition to 415 pit wells, and the price of the crude oil was 45 copecks per pood (about £3, 10s. per ton). The following tabular statement shows the growth of the industry from the time when the monopoly was abolished:—

#### PRODUCTION AND PRICE OF CRUDE PETROLEUM.

	Tons.	Price per Ton.
1873.....	61,000	8 9
1874.....	78,000	6 3
1875.....	94,000	15 6
1876.....	194,000	7 9
1877.....	242,000	12 6
1878.....	320,000	8 8
1879.....	370,000	6 3
1880.....	420,000	3 8
1881.....	490,000	2 6
1882.....	680,000	.....
1883.....	800,000	2 6 to 0 34
1884.....	1,130,000	.....

The production of crude petroleum in the United States for 1884 has amounted to about 3 million tons, and the price has ranged from about 16/- to 32/- per ton.

The specific gravity of the crude oil is usually

between '870 and '875; some wells have, however, yielded oil as heavy as '885, and others oil as light as '850. The specific gravity of the oil first obtained from Nobel's No. 18 well was '860, but upon the well being deepened the specific gravity fell to '854. The specific gravity of the crude oil now found in Pennsylvania ranges from about '800 to about '820. I have placed on the table samples of Russian and United States crude oil for comparison.

The crude oil is in the first instance conducted from the well through wooden channels to ponds or lakes, where it deposits the sand held in suspension, and it is then pumped into storage tanks prior to being piped to the refineries.

Formerly—that is, up to 1875—the transport of the oil to the refineries took place exclusively in the Persian carts or “arbas,” I have already mentioned. These strange-looking vehicles are entirely constructed of wood, the body of the cart simply resting on the wooden axle, and the latter revolving with the wheels, which are often 8½ to 9 feet in diameter. The felloes of the wheels, being unprotected by tyres, are made of great depth to allow for the rapid wear to which they are subjected in traversing the rough roads, and the wheel becomes in use of smaller and smaller diameter until its dissolution, which generally seems to occur unexpectedly at the most inconvenient time. In these carts two casks were conveyed, one in the body of the vehicle, and the other slung beneath the axle. Thousands of these carts were in use prior to the era of pipe-lines: it is stated that as much as £100,000 per annum was paid for thus transporting the crude oil.

The first pipe-line from the wells to the refineries was laid by Messrs. Nobel Brothers, in the face of the most determined opposition on the part of the proprietors of the “arbas,” who recognised that their business was threatened with extinction; and it is evidence of the lawlessness prevailing in the Caucasus that Messrs. Nobel were compelled to erect a line of watch-houses, wherein they stationed armed men to guard their pipe. Pipe-lines have some time since been accepted by the native carters as a necessary evil, but there is still much jealousy among the well-owners and refiners, and as the Tartars have no samples about taking life, it is not safe for the visitor to traverse the district around Baku after dark without an armed escort, while even in daylight it is well to carry a revolver.

At the present time there are seven pipe-lines for the conveyance of crude oil, the two largest, which are of the respective diameters of 6in and 5in., being the property of Messrs. Nobel Brothers. A certain amount of crude oil is also transported to the refineries by rail. More than 700 millions of gallons per annum could thus be delivered at the refineries, the Nobel Company's two pipes alone having a carrying capacity of 176 million gallons per year. Several telephone wires connect the wells with the refineries.

## II.—REFINING.

There are about 200 refineries in the Tcherni Gorod or Black Town, at Baku, but at the time of my visit not more than 50 or 60 were in operation. The works range in size from the primitive Persian refinery, with a couple of stills, to the gigantic establishment of Nobel Brothers, and at all these works petroleum residuum is the sole fuel used.

Messrs. Nobel's plant, for separating the burning oil or kerosene, as we may conveniently term it, consists of a large number of stills, each of the capacity of 4400 gallons, arranged in groups or series of not more than 25, and worked on the principle of continuous distillation,

a stream of oil flowing through the entire series. Mr. Nobel informs me that this method of distillation is specially adapted for Russian petroleum, since from such oil only a comparatively small percentage of kerosene is obtained, and the residuum flowing from the stills is almost as fluid as the crude petroleum. The products of distillation are first separated into three fractions, termed respectively benzene, sp. gr. '754; gasolene, sp. gr. '787; and kerosene, sp. gr. '820 to '822. There is but little demand for the lighter products, and though a certain quantity is sold for detergent and manufacturing purposes, and a further quantity is employed by Messrs. Nobel as fuel, much has to be burned in waste to get rid of it. The kerosene distillate is pumped into lead-lined iron tanks, termed agitators, of the capacity of 57,000 gallons, where it is treated with about 1½ per cent. of sulphuric acid. The acid is forced up to the top of these tanks (which are above ground) by air pressure, and is distributed through perforated coils of leaden pipes, so that it falls through the oil in fine streams. The oil and acid are then subjected to agitation by introducing a blast of air at the base of the tank. After this treatment the acid is allowed to subside, and the oil is drawn off into a similar sized iron tank without lead lining, standing at a lower level. In this tank, which is furnished with a similar method of agitating, the oil is treated with a solution of caustic soda, and is afterwards washed. Fresh water being very scarce at Baku, sea water is used for washing the oil as well as for the condensers. The sea water is brought into Messrs. Nobel's refinery from the Caspian by an aqueduct 5 feet in diameter, the intake being 7 feet below the sea surface, and 300 feet from the shore. The temperature of the water in summer is about 22° R. (82° F.). The kerosene is run from the washing agitators into settling tanks, where it deposits water, and thence is pumped into storage tanks (one of which at Messrs. Nobel's works holds 1½ million gallons), preparatory to being placed in the tank steamers for conveyance to the mouth of the Volga. The whole process of treatment of the distillate occupies from 15 to 16 hours. The sulphuric acid used by Messrs. Nobel is made by them in a separate factory, where 3100 gallons per 24 hours can be turned out. The sulphur was formerly imported from Sicily, but is now obtained from Tchirkat in Daghestan, near the port of Petrovsk on the Caspian. There is at Baku another factory, where sulphuric acid for the use of the other refiners is made. Although there are no laws or regulations in Russia prescribing a test for petroleum, Messrs. Nobel prefer to make a burning oil having a flashing point considerably above that which experience has shown to be sufficient to insure safety in the case of American kerosene, Nobel's oil having a flashing point of about 32° C., when tested by the German modification of Sir Frederick Abel's well-known apparatus. The oil has a specific gravity of about '821, and is almost free from colour and odour. Of this oil the crude petroleum yields only about 27 per cent., but a much larger percentage of oil of lower flashing point or higher specific gravity could be obtained. Of oil absolutely free from colour, of sp. gr. '823, and flashing point 50° C., Abel-Pensky test, the crude oil yields about 22 per cent. At another refinery which I visited (that of the Caspian Company), I was informed that the following grades of kerosene were made:—

Quality.	Sp. Gr.	Flashing Point.
1.	'815	30° C.
2.	'820	25° C.
3.	'821-'822	22° C.

Of the first quality, some of which is exported from Batoum, the crude oil is stated to yield 20 per cent.;

of the second quality, sold in Russia, 33 per cent.; and of the third quality, sold locally for consumption in the Caucasian district, 38 per cent. The crude petroleum of the United States yields not less than 70 per cent. of kerosene.

The residue in the stills after the kerosene has been volatilised has a sp. gr. of about 1.003, and is known by the Russian name of *astatki*, or by the Tartar name of *masit*. It is usually stored in large excavated tanks, lined with masonry. Messrs. Nobel have a cylindrical tank of this description holding 11 million gallons.

From the *astatki*, lubricating oil is obtained by distillation, but in Messrs. Nobel's works only about 10 per cent. of the *astatki* has hitherto been thus dealt with. Of the remainder, Messrs. Nobel use a small portion for the heating of their stills and boilers, and sell the greater part as fuel. The *astatki* yields about 30 per cent. of lubricating oil, and about 15 per cent. of what is known as solar oil (sp. gr. about 1.860 and flashing point about 220° F.—closed-vessel test). The latter is a product intermediate in sp. gr. and flashing point between the kerosene and the lubricating oil, and is capable of being burned in suitable lamps, two of which I have on the table. It has by some refiners been termed *pyro-naphtha*, and Messrs. Ragosine have introduced it as a "safety burning oil," but so far it has been difficult of sale, and it is usually returned to the *astatki* and thus employed as fuel. I have on the table specimens of the various products to which I have referred. The crude petroleum of Baku differs from that of the United States in containing little or none of the solid hydrocarbons; some of the crude oil of this district appears, in fact, to be practically free from solid hydrocarbons, and I believe that it is the largest quantity that any of it contains. On the other hand, the petroleum obtained from Messrs. Nobel's wells in the Island of Tcheleken, on the opposite side of the Caspian Sea, yields as much as six per cent. of solid hydrocarbons. It is well known that the paraffin obtained from American petroleum is a source of considerable profit, but while the Baku refiner is at a disadvantage in this respect, he is enabled to make without difficulty or expense a lubricating oil, which bears exposure to a temperature below zero of Fahrenheit's scale without becoming solidified.

There are in the Baku district other refineries besides those situated in the Black Town. One of these (Kokereff's) is at Surakhani, on the site of the Eternal Fires, the distillery immediately adjoining the temple I have already described. This refinery was built with the view of using the natural petroleum gas as fuel, and elaborate arrangements were made for collecting the gas and conducting it beneath the stills, but when I visited the distillery, *astatki* was being used as fuel. The abundance of natural gas in the neighbourhood of this refinery is shown by the fact that the gas is now, as it has been from time immemorial, largely used in lime burning. There is plenty of limestone rock, and the lime burners simply turn up the surface of the ground and apply a light to the gas.

Messrs. Nobel's refinery is not only the largest, best constructed and best conducted at Baku, but it compares, I think, on the whole favourably with any I have seen in the United States. Portions of it are fitted with Siemens's electric light, and some idea of its magnitude may be gathered from the fact that it contains no less than 45 miles of piping. It covers from 75 to 80 acres, but the total area of the works, if the ground occupied by the houses of the employes is included, is 120 acres. In this connection I may mention that Mr. Nobel has erected a number of handsome dwellings and a club house for the general manager of the works, the chemists and engineers,

and has planted gardens which are irrigated with water brought from the Volga.

Mr. Peacock estimates that 8000 men are employed in the petroleum industry at Baku, the common labourers being nearly all Tartars, Persians and Armenians, while the coopers, carpenters and other skilled workmen are Russians, Finns and Swedes. The wages of the former class are as low as 10d. per day or about 25s. per month, while those of the latter class range from £3 to £6 per month.

The following table shows the amount of kerosene manufactured during the last 13 years by Messrs. Nobel Brothers and the other refiners:—

Years.	Nobel Brothers.	All other Refiners.	Total.
	Tons.	Tons.	Tons.
1872	16,400	16,400	16,400
1873	24,000	24,000	24,000
1874	25,000	25,000	25,000
1875	32,000	32,000	32,000
1876	100	35,000	35,100
1877	2,500	75,000	77,500
1878	15,000	95,000	110,000
1879	9,000	104,000	113,000
1880	24,000	126,000	150,000
1881	50,000	133,000	183,000
1882	72,000	120,000	192,000
1883	166,000	105,000	266,000
1884	157,100	194,500	318,100

The price at Tsarsitsin was in 1878, 3s. per five gallons, and is now about 1s. 3d.

The total exports of kerosene from Russia for 1884 amounted to 37,900 tons, of which Nobels manufactured 15,000 tons.

I estimate the quantity of kerosene manufactured from American crude petroleum in 1884 at more than two million tons.

The following tabular statement shows the increase in consumption of kerosene in Russia per head of the population. The figures are Russian pounds:—

#### CONSUMPTION PER HEAD OF POPULATION.

1872	1873	1874	1875	1876	1877	1878	1879	1880	1881	1882
169	176	193	230	221	307	326	418	415	611	614

The distilling plant of the Nobel Company would enable them to make per 24 hours, 200,000 gallons of kerosene, 80 tons of lubricating oil, and 1200 tons of liquid fuel, equal to a yearly production of at least 65,000,000 gallons, 27,000 tons, and 450,000 tons of the three products respectively. We have already seen that the quantity of kerosene made by this firm last year was 157,100 tons, equal to 42,700,000 gallons, and it is estimated that the sales of lubricating oil and residuum for the same period amount to 2000 tons and 250,000 tons respectively. If, therefore, Nobel's works were continuously in full operation throughout the year, there would remain a surplus available for export of more than 22 million gallons of kerosene, 24,000 tons of lubricating oil and 200,000 tons of liquid fuel.

The native petroleum industry is protected in Russia by an import duty on American kerosene of 55 copecks per pool, equal to about 3d. per gallon, and since 1873 the imports of American kerosene into Russia have diminished year by year. At the present time practically the whole of the kerosene burned in Russia is manufactured at Baku.

The quality of the kerosene made from Russian petroleum has been the subject of much discussion. When the oil was first introduced into Europe its high specific gravity led to the belief that it would not be found to burn well in ordinary mineral oil lamps. The fact was, however, overlooked that the crude oil yields so small a percentage of kerosene, that this product is necessarily very homogeneous, the various hydrocarbons composing it not differing very widely in specific gravity, boiling point and other characteristics. This feature is clearly shown by the

following results, which I have obtained in fractionally distilling samples of Russian and American crude petroleum and kerosene obtained therefrom. A measured quantity of the liquid was distilled, and each distillate was  $\frac{1}{10}$  by volume of the quantity taken for distillation:—

	Baku Crude Petroleum. (sp. gr. 373)	United States Crude Petroleum. From Bradford District. (sp. gr. 319)	From Parker District. (sp. gr. 354)
1st fraction—sp. gr.	787	725	724
2nd .. ..	812	753	742
3rd .. ..	839	776	769
4th .. ..	855	781	778
5th .. ..	861	822	798
6th .. ..	848	836	818
7th .. ..	839	837	825
8th .. ..	817	839	831
9th .. ..	857	843	846

*Remarks.*—The distillation was throughout conducted without passing steam into the retort, and there was therefore, especially in the case of the Baku petroleum, some decomposition or “cracking” of the hydrocarbons, accompanied by the evolution of gaseous products, and deposition of carbon. This accounts for the low sp. gr. of the latter fractions of the Baku oil, and for the fact that there was not, in every case, sufficient of the 10th fraction to admit of the sp. gr. being taken. It was, however, only desired to indicate that the Baku petroleum yields comparatively little kerosene, and no arrangements were, therefore, adopted to secure the distillation of the lubricating oil undecomposed.

	Russian Kerosene. (sp. gr. 822)	American Kerosene (sp. gr. 805)
1st fraction—sp. gr.	783	748
2nd .. ..	796	759
3rd .. ..	803	778
4th .. ..	814	792
5th .. ..	827	802
6th .. ..	831	812
7th .. ..	837	822
8th .. ..	838	831
9th .. ..	846	838
10th .. ..	864	849

A reference to the tables will show (*a*) that the Russian crude petroleum contains a comparatively small proportion of the lighter hydrocarbons, and (*b*) that in the case of the Russian kerosene there is less difference between the sp. gr. of the lightest and heaviest fractions than in the case of the American kerosene.

lamp was fitted with a Hinks's duplex burner, and two varieties of wick were used. What is termed the American wick was a wick of long-staple cotton loosely woven, the English wick being a comparatively hard, tightly woven wick such as is commonly employed in this country. I may take this opportunity, of stating that I have not found any exception to the rule that all mineral oils burn far more satisfactorily as well as more safely, when a wick of the character of the American wick referred to is used, and I am of opinion that too little attention has hitherto been paid to this important adjunct to the lamp.

It will be noted that the Russian oil did not with either wick give as much light as was afforded by the sample of American oil, but on the other hand there was considerably less diminution in the light as the level of the oil in the reservoir of the lamp fell, and I may state that the latter feature has characterised all the comparative tests I have made of the two kinds of oil. I have tested the Russian oil in various other forms of burner used in this country and on the Continent, and except in the case of a burner in which a metal cone was substituted for the usual glass chimney, I have found that it burns satisfactorily. I have therefore no hesitation in saying that it is adapted for use in ordinary mineral oil lamps.

Russian kerosene is, as I have stated, almost free from colour; that which is manufactured by Messrs. Nobel being what is technically termed superfine white, according to the method of testing and standards of the Petroleum Association. Formerly the colour of refined petroleum was estimated by comparing it with that of a standard sample, the two oils being contained in bottles of the same size. Several years ago I had an apparatus constructed for colour testing, which is now on the table. It consists simply of an arrangement for holding two tall glass cylinders above a mirror in such a position that the images of the bottoms of the cylinders are presented side by side. The oil to be tested being placed in one cylinder, and a standard sample in the other, it is easy to make an accurate comparison of the reflected discs, which are, of course, tinted in proportion to the colour of the liquids. I found this mode of estimating colour preferable, in the case of

	RUSSIAN KEROSENE.		AMERICAN KEROSENE.

Grains of oil consumed per candle-light per hour .....	53.6	51.1	51.6	51.7

I have made a large number of photometric tests of Russian kerosene burning in ordinary lamps in comparison with American kerosene, on various occasions during the past eighteen months, and in the following table I give some of the most recent results obtained, the Russian oil used in these experiments being of Nobel's manufacture, and the American oil ordinary kerosene of good quality. The test

a fluorescent liquid like petroleum, to that of looking down upon the surface of the oil while the tube or cylinder is held over a white surface. Soon after I commenced the regular use of this apparatus, Mr. Robert P. Wilson, a member of the Committee of the Petroleum Association, invented and patented (in 1870) the chromometer now largely used in the trade. This instrument consists of two tubes arranged side

by side and furnished at the lower end with a small mirror, by means of which light may be reflected upwards through them, each tube having a screw cap with glass centre. Above the upper ends of the tubes is fixed a small box containing two pairs of prisms, and above this is an eye-piece.

Up to this time it had been the custom to use standard samples of kerosene for comparison; but these were liable to alter in colour, and it was by no means the least valuable feature of Mr. Wilson's instrument that glass standards were substituted for the liquid standards previously employed. In using the apparatus, one of the two tubes is completely filled with the oil to be tested, and beneath the other tube is placed one of the standards, consisting of a disc of stained glass about the size of a shilling. The mirror is then adjusted so as to project the light through the tubes, and upon looking into the eye-piece a circular field divided down the centre is seen, the halves being tinted to an extent corresponding with the colour of the oil and of the glass standard respectively. The dividing line is formed by the edges of the two pairs of prisms referred to, and the prisms are employed to bring the light from the two tubes into one eye-piece, in the manner shown in the diagram (see Fig. 2):—

FIG. 2.

Wilson's chromometer was, after a sufficient trial, adopted in 1872 by the Petroleum Association, and is

FIG. 3.

now in use in America and on the European continent, as well as in this country.

I have on the table a German modification by Stammer of this instrument (Fig. 3). In Stammer's apparatus, which in principle resembles the chromometer already described, the tube containing the oil under examination is open at the top, and is fitted with an inner empty tube, also open at the top and closed at the bottom by a disc of glass. The inner tube is in the first instance raised to the highest point, and a glass standard somewhat paler in colour than the whole column of oil having been selected, the inner tube is lowered, the oil being gradually displaced and the column of liquid shortened, until the two colours match, when the extent of shortening is read off on the scale. The precise colour of the oil can thus be recorded.

Lubricating oil made from Baku petroleum was, I believe, first introduced into England by Mr. Victor Ragosine, in 1877, and is now sold by the firm of Ragosine and Co., under the registered names of "Oleonafta" or "Ragosine Oil," in Germany, France, Austria, and Belgium, as well as in this country. This firm has two refineries on the Volga, north of Nijni Novgorod, capable of turning out a quarter of a million barrels a year. The crude oil and residuum are brought from Baku *via* the Caspian and Volga, and the refined products are conveyed to the consuming countries *via* the Volga and maritime canal to Cronstadt. The water route, though circuitous, is economical, and is likely to be adhered to until the raw material can be piped from Baku to the shores of the Black Sea. The imports of Ragosine lubricating oil into France and Belgium since 1877 amount to 187,000 barrels.

Russian lubricating oil, besides being, as a rule, practically free from solid hydrocarbons, and therefore bearing exposure to very low temperatures, without becoming solidified and thus clogging the bearings of machinery, has a remarkably high viscosity in relation to its specific gravity. This characteristic is very clearly exhibited in the following tabular statement of results which I have obtained in determining the viscosities of samples of Russian and American lubricating oils for the purpose of comparison:—

	Viscosity		Loss in	
	at 70° F.	at 120° F.	Viscosity	per cent.
Russian oil (sp. gr. '913).....	1100	165	88	
American oil (sp. gr. '916).....	231	66	71	
Russian oil (sp. gr. '907).....	619	125	79	
American oil (sp. gr. '907).....	171	58	65	
Russian oil (sp. gr. '898).....	153	56	67	
American oil (sp. gr. '898).....	81	49	59	
A sample of refined rape oil (for comparison).....	321	112	65	

It has been pointed out that although Russian lubricating oil has a very high viscosity, it rapidly loses its "body" upon being raised in temperature, and a reference to the viscosity figures for temperatures of 70° and 120° F. in the table will show that this is the case, the loss in viscosity between the two temperatures being in the case of a sample having a sp. gr. of '907, 79 per cent. against 66 per cent. in the case of an American sample of the same sp. gr. Where it is desirable, however, to employ an oil of high viscosity at comparatively low temperatures, as in the lubrication of slow running heavy machinery, the Russian product is superior to the American. Moreover, it may be urged that it is because of its high viscosity that Russian lubricating oil is so much affected by a rise of temperature, for it will be noted that in the case of the American oils, as well as in that of the Russian oils, the diminution in viscosity is in proportion to the viscosity, the oils of greatest body being most affected. It is well known that mineral lubricating oils possess, as compared with fixed oils, the advantage of not being liable to

decomposition under the influence of high pressure steam, or to oxidation. They are, therefore, well adapted for the lubrication of engine cylinders, and cotton waste used to absorb them is not liable to spontaneous combustion.

I have already stated that petroleum residuum or astatki is the only fuel employed in distilling petroleum at Baku. The most simple manner in which this fuel can be used is that which is adopted in the primitive Persian refineries, where the fluid is allowed to trickle upon the floor of the furnace beneath the still, and to burn there. The combustion is, however, under these circumstances, very far from complete, and volumes of black smoke are evolved. This smoke hangs in dense clouds over the Tchorini Gorod or Black Town of Baku, and is particularly offensive and destructive of wearing apparel and furniture, as it is so highly charged with oily particles of carbon that it may, in fact, be termed vaporous black paint. At the Nobel Company's refinery and some other efficient arrangements for the combustion of the astatki are adopted, and little or no smoke is evolved. Before I proceed to describe these arrangements, it will be convenient to consider briefly the development of the use of liquid fuel. As long ago as 1862 patents were taken out in the United States by Bidley, by Shaw, and by Linton, for the use of liquid fuel, and in 1864 experiments were made, at Woolwich, with an apparatus invented by Richardson. Aydon and Shpakovsky in 1865 independently devised arrangements for injecting the fuel into the furnace in the condition of spray, the former using at first superheated steam, and afterwards ordinary steam for the purpose, while the latter employed a blast of air. In the same year, Professor Rankine gave his attention to the subject, and in 1877, H. St. Claire Deville commenced a number of experiments at the request of the Emperor Napoleon III. Deville's apparatus was put to a practical test in Russia by Kamensky, and afterwards by Lentz in 1869, but proved a failure. In 1879 experiments were made at the Brooklyn Navy Yard, in the United States, with a mixture of crude petroleum and pitch, blown into the furnace by a jet of superheated steam, and a very high temperature was obtained, iron being melted in 10 minutes and glass in 2 hours, as compared with 2 hours and 16 hours respectively when coal was employed as the fuel. In 1870, a steamer called the "Alexai" was fitted with an improved apparatus by Shpakovsky, and a successful result was obtained. Meanwhile, Lentz had also improved his apparatus, and either the Lentz oil burner, or some modification of it, is now employed in the better conducted refineries at Baku. The diagram (see Fig. 4) shows the construction of one of these modifications (Kaufmann's) which has been adopted by the Russian Government for use in torpedo boats, the cylindrical flame afforded being well suited to the boilers of these boats. The astatki and steam meet at C D (see Fig. 4), where, by means of two screws, a fissure is opened through which they escape. The apparatus consists essentially of an arrangement for spraying, or, as it is termed in Russia, pulverising the oil by means of a jet of steam, a tongue of flame being in this way projected into the furnace. In thus using liquid fuel for the generation of steam, it is of course necessary in the first place to take a supply of steam from a small auxiliary boiler, or to raise steam by the use of wood or other fuel. The greatest objection to this kind of apparatus lies in the fact that the intensely hot pointed flame is liable to have a prejudicial effect upon the boiler, and it has been found necessary to employ screens of fire-clay, against which the flame is directed. Minor objections to the system are that it is wasteful (for, besides the loss of steam, the heat obtained from the astatki is from

10 to 20 per cent. less than it is capable of yielding), and that it is noisy, the roar of the blast being, in some cases, very objectionable. Nevertheless, the apparatus is very largely used, more than a hundred steamers on the Caspian and Volga, including those employed by the Nobel Company for the conveyance of kerosene, being fitted with it. Nobel's steamers, I may mention, consume 20 tons of astatki on the voyage from Baku to the mouth of the Volga and back. It is a novel experience to look into the stoke hole of a Caspian oil-burning steamer. Instead of griny toiling firemen and coal trimmers, there is a single attendant whose sole duties consist in regulating the cocks supplying the astatki and steam. Consulting the pressure gauge from time to time, this attendant is able so to regulate the heat that there is neither a scarcity nor a superabundance of steam.

Liquid fuel is also now largely used on the Russian railways, including the Trans-Caucasian and the Griazi-Tsaritsin lines. In regard to its employment on the latter railway, Mr. Crquhart stated last year in *Engineering* that the combustion was smokelessly perfect, and that a practical evaporation of 12 to 13 lb. per lb. of petroleum was possible. He added that 3 or 4 tons of astatki can be run into the tank on the tender in about 4 minutes, the supply of water being taken in at the same time.

While travelling by train from Baku to Batoum, I noticed that although no smoke was emitted by the locomotive, there was occasionally a disagreeable odour of imperfectly consumed petroleum, but I have no doubt, that when the arrangements for burning astatki in such boilers are perfected, this source of annoyance will be removed.

Experiments with a stationary boiler in Messrs. Nobel's works show that one pound of astatki sprayed as described, vaporises 12 lb. of water while the same quantity of coal only vaporises from 7 to 8 lb. in the same boiler.

In consequence of the objections attaching to the steam-spraying method of burning astatki, Mr. Nobel has made a large number of experiments with the object of devising an apparatus in which satisfactory combustion of the fuel might be attained without the use of steam, and has recently patented an arrangement which appears to answer the purpose admirably. The apparatus consists essentially of a series of shallow receptacles or troughs, so arranged one above another at the mouth of the furnace, that the burning astatki flows by successive stages from the highest to the lowest. I have on the table one of these troughs, and the diagrams (Figs. 5, 6, and 7) illustrate a more recent form, as well as the method of applying the apparatus to the heating of steam boilers.

With this apparatus no less than 14 lb. of water can be vaporised by the combustion of 1 lb. of astatki, the heating effect of the liquid burned under the two conditions described, as compared with coal being, therefore, as follows:—

Practical evaporation per lb. of fuel in a steam boiler at Messrs. Nobel's works.	
Coal.....	7 to 8 lbs.
Astatki steam sprayed.....	12 ..
Astatki burned with Nobel's system of troughs.....	14 ..

The most remarkable results have, however, been obtained in the use of Nobel's trough burner for metallurgical purposes. In a furnace at Mr. Nobel's engineering works at St. Petersburg I saw wrought iron reduced to a state of fusion, and horse-shoes, spanners, toothed wheels and other articles of soft iron can thus be easily and cheaply produced by casting in moulds. I have on the table specimens of this kind of iron work, notably a spanner, which has been bent double under a hammer without showing any signs of fracture. These results have been obtained

FIG. 5.—Nobel Burner (Trough).

FIG. 7.—Nobel Trough Burner applied to Vertical Steam Boiler.

FIG. 6.—Nobel Trough Burner applied to Horizontal Steam Boiler.

without any heating of the air supply; and there can be no doubt that if the air required for the combustion of the fuel were previously brought in contact with heated surfaces, much higher temperatures might be commanded. The difficulty of finding sufficiently intractable materials for the furnaces has, however, hitherto stood in the way of making experiments in this direction. Liquid fuel is thus practically applied for the fusion of iron and brass in Baku; and it is found that old scrap iron may, in this way, be converted into a valuable soft grey pig iron. The employment of astatki for metallurgical operations is largely extending, and the freedom of the fuel from phosphorus and sulphur gives it a great advantage. The cost of astatki at Baku is about 2s. 6d. per ton, and it can be delivered at Tsaritsin, on the Volga, at about 8s. per ton. It is now much used in Moscow, and in localities as far distant as Stockholm and Teheran, no less than 1,500 tons per annum being shipped to Persian ports. Among the advantages of liquid fuel for steamships may be mentioned economy of space in stowage, as well as of labour and time in placing the fuel on board and supplying it to the furnaces, and the smokeless character of the combustion; the last-named being an important point in the case of ships of war.

We have now to consider a feature of the Russian petroleum industry, which is of special interest to the chemist, and seems destined to be of great commercial importance. I refer to the employment of astatki as a source of benzene, anthracene and naphthalene. The process employed can scarcely be said to have passed beyond the experimental stage; but the apparatus I saw was of considerable size; and I am assured that the trials have been conducted on a scale sufficiently large to demonstrate conclusively the practicability of the mode of operating. The astatki is decomposed in a cupola regenerative furnace, which has been patented by Mr. Nobel, to whom I am indebted for the following interesting particulars of the results obtained. The first destructive distillation gives from 30 to 40 per cent. of tar, containing from 15 to 17 per cent. of 50% benzol. By a second destructive distillation of the heavy oils remaining in the tar after the separation of the benzol, 70 per cent. of tar is obtained, containing from 7 to 10 per cent. of 50% benzol, 16 per cent. of naphthalene, 2 to 3 per cent. of dry "green grease" (or 30% anthracene), and 24 per cent. of pitch. There is also obtained in the process 75 to 100 cubic feet per cubic foot of astatki of gas having an illuminating power five times greater than that of coal gas. The regenerative furnace is first heated to 1000° C., astatki being, of course, used as the heating agent, and when it has become cooled in the process of decomposing the astatki it is again similarly heated, the gas remaining in the furnace and the coke deposited on the hearth being utilised as fuel. The furnace is stated to remain in working order without cleaning for twelve months. The world's consumption of benzol is probably not less than 7000 to 8000 tons per annum. London gas-tar contains about 1 per cent. of 50% benzol and 1 per cent. of 30% anthracene.

### III.—DISTRIBUTION.

The most remarkable illustration of the forethought, energy and enterprise which have throughout characterised Mr. Ludwig Nobel's action in the petroleum trade is afforded by the admirable system of transportation and distribution, which he has elaborated. It is well known that refined petroleum is usually carried in casks, holding about 40 gallons, or in tins of four gallons enclosed in twos in wooden cases. The latter package is comparatively costly, and is only employed in the case of oil intended for use in hot climates; and as Russia produces

but little timber available for barrel making, the difficulty of transport appeared likely to seriously interfere with the development of the trade. Under these circumstances Mr. Nobel conceived the plan of conveying the oil in bulk from Baku in tank steamers, tank barges, and tank railway waggons, to large storage tanks, whence it could be distributed in comparatively small quantities, in barrels which could be returned to be refilled. This system has proved perfectly successful; and it is not too much to say that without its adoption the petroleum trade in Russia could not have reached its present magnitude. Tank railway cars had been employed for the conveyance of crude petroleum in the United States, long before Messrs. Nobel Brothers commenced using them in Russia; but I am not aware that this method of transporting refined oil had been adopted in America. The credit, however, of having carried to a successful issue the shipments of petroleum in tank steamers, undoubtedly belongs to Mr. Nobel, previous experiments in this direction having proved unsuccessful.

The tank steamers employed by Messrs. Nobel Brothers were constructed at Motala in Sweden, and were floated in halves through the excellent canal system which Russia possesses to the Volga, where the forward and aft portions were united. These vessels are about 250 feet in length by about 28 feet in breadth, and have a draught when loaded of from 10 to 12 feet. The whole of the bows and forward part of the steamer forms one large cistern, furnished with two longitudinal bulkheads, and several transverse bulkheads to prevent oscillation of the liquid when the vessel is rolling in a heavy sea. The engines and boilers are amidships, and aft of these are two cylindrical vertical tanks, of a diameter about equal to the beam of the vessel, rising somewhat above the level of the deck. The general appearance of the vessels is shown by the photograph on the table. The total capacity of the tanks is about 225,000 gallons (equivalent to 5,500 barrels of 40 gallons each). The steamers are driven by screw propellers, and the engines are of 120 horse power, nominal. The fuel used is astatki or petroleum residuum, and the speed attained is about 10 knots per hour. Of such steamers Messrs. Nobel Brothers have, on the Caspian, 12. There are also half-a-dozen smaller steamers owned by other firms.

While loading, the steamers lie alongside piers extending into the sea from the neighbourhood of the refineries, the oil being conveyed on board through 8-in. pipes, and the cargo of oil can thus be placed in the vessel in 4½ hours.

From Baku to the mouth of the Volga is a voyage of a couple of days, the distance being about 460 miles; but the Caspian is a stormy sea, as I found to my inconvenience, and in the short trips which the steamers make the system of tank transportation has been severely tested, and has been proved to be free from risk. It is true that the prevailing winds on the Caspian are either north or south, and, therefore, dead ahead or astern; but if tank steamers can traverse this sea without accident, there is probably no reason why they should not safely cross the Atlantic, and I doubt not that in time American petroleum will be shipped in bulk.

The Volga at its wide mouth is extremely shallow, and the tank steamers can proceed no further than a locality termed Nine Feet Soundings, about 20 miles from land, and 80 miles below Astrakhan. Here the oil is transferred to tank barges, in which it is conveyed to Tsaritsin (a distance of 284 miles from Astrakhan) or other distributing centres on the Volga, the transport of the oil from the Baku refineries to Tsaritsin occupying six days. There are 38 tank barges on the Volga, of which 20 are owned by Messrs.

Nobel Brothers. At Tsaritsin Messrs. Nobel Brothers have 15 storage tanks (holding collectively six million gallons), railway sidings, cooperage, etc., and the electric light is employed to facilitate work at night. There are also at this place some 30 tanks, of an aggregate capacity of nearly nine million gallons, belonging to the Caucasus and Mercury Company, and other firms; but many of these tanks are for the storage of residuum, while all except one of Messrs. Nobel's tanks are for burning oil.

From the storage tanks at Tsaritsin the oil is run into tank railway waggons, or barrelled, for conveyance by rail into the interior of Russia. Messrs. Nobel have on the Tsaritsin-Griazi railway 1,500 tank waggons, similar in form to those used in the United States, each waggon holding about 2,600 gallons of oil. A train is usually made up of 25 waggons, and thus Messrs. Nobel have 60 trains engaged in the conveyance of refined petroleum from Tsaritsin to their storage tanks throughout Russia. The railway company have also a considerable number of tank waggons of their own for the conveyance of the petroleum of other firms.

Messrs. Nobel have at Tsaritsin a barrel factory capable of turning out 500 barrels per day, much of the wood used being brought from Siberia by way of the river Kama.

The Nobel Companies have established their principal storage and distributing centre at Dominno, near Orel, in Central Russia, where they have tanks capable of holding 18,000,000 gallons. They have also extensive tankage at Moscow, St. Petersburg, Warsaw, Saratow, and 23 other places, chiefly in Russia, the total storage thus provided being more than 26 millions of gallons. The necessity for providing for so large an accumulation arises from the fact that the Volga navigation being closed from the latter part of November to April, the year's supply must be conveyed into the interior of Russia and placed in storage during eight months. An interesting feature of the working of this system of tank-waggon distribution may be witnessed at Messrs. Nobel's office in St. Petersburg. A map of Russia is marked with the various depôts and connecting railroads, and the clerk in charge being furnished from time to time throughout the day with telegrams informing him of the movements of the 60 petroleum trains, indicates the position of each train on the map by means of a small flag.

Until recently Messrs. Nobel were fully occupied in supplying the home demand for burning oil, but during the past year they have transported a considerable quantity across Russia into Germany, Austria and Belgium, and it is contemplated to ship oil from Libau in tank steamers.

The following estimate of the cost of Russian kerosene delivered in Stettin has been published by the Nobel Company:—

	Per Gal.
Cost of the kerosene delivered at Tsaritsin on the Volga, including general charges and a reasonable profit.....	1d.
Railway freight in Nobel's tank cars from Tsaritsin to Libau.....	1d.
Charge for wear and tear of tank cars.....	1d.
Freight from Libau to Stettin.....	1d.
Proportionate cost of barrel at Stettin, with storage, discharging and leakage.....	1d.
Total cost.....	6d.

Other firms have followed the example of Messrs. Nobel in the organising of bulk transport. The Caucasus and Mercury Company propose to provide tank steamers and barges capable of conveying 120,000 tons of oil from Baku to Tsaritsin on the Volga during the eight months that the navigation

of the river is open, and have arranged with a Russian company for the conveyance of the oil from Tsaritsin by rail, and its distribution throughout Russia.

A glance at the geographical position of Baku will show that there are two principal outlets for the petroleum to western countries, viz., by the Volga, and across the Caucasus to the shores of the Black Sea. Hitherto I have dealt only with the former outlet, but as the latter promises to be at some future time of vast importance, I propose to describe it in detail. It is well-known that a line of railway, 560 miles in length, now connects Baku with the port of Batoum. A portion of this line was constructed many years ago, but the section connecting Baku and Tiflis has not very long been completed. It was anticipated that the railway from Baku to Batoum would have furnished a means of transport for large quantities of petroleum, but, unfortunately, from motives of economy, the older portion of the line was carried over what is known as the Suram Pass which has an elevation of 3,000 feet above sea level, and the gradient being in some places as much as 1 in 22, a train is limited to only six tank cars, though two Fairlie engines are used to draw it up the incline. The line also being a single one the traffic is congested, and I was informed that the transport of petroleum from Baku to Batoum, which costs about 1d. per gallon, has recently occupied from four to fourteen days. In order to overcome the difficulty, it is proposed to establish a storage depôt on the Baku side of the pass about 160 miles from Batoum, where the tank cars would discharge their contents, and from this point to lay a pipe line over the pass to Batoum so that the oil may be pumped up to the highest point and allowed to flow down to the shores of the Black Sea. It is the opinion of competent persons with whom I discussed the subject, that before Batoum can become a very important place of shipment for Baku petroleum, either the pipe line to which I have referred must be constructed, or the railway improved by laying a second line of rails and making a tunnel five miles in length through the Suram Pass.

The cost of the pipe line is estimated at three millions of roubles, while the tunnel would probably cost eight to ten millions of roubles. In any case extensive tank storage must be provided at Batoum, and it is thought that if, pending the construction of a pipe line or tunnel, there were adequate means of receiving and storing the oil at this port, the present railroad, if properly managed and provided with the necessary rolling stock, would be sufficient for the transport of from 40 to 50 millions of gallons per annum. Mr. Burkhardt of Batoum, informs me, in a letter received recently, that during the year 1884 there were shipped from that port about 14,500 tons of kerosene, 4500 tons of lubricating oil, and 4700 tons of asphalt or residuum; a total of rather more than 6,400,000 gallons.

When I travelled over the line there were nominally 400 tank waggons for the conveyance of petroleum, but I was informed that less than 300 were available for use. I have, however, quite recently learned that the Russian Government has authorised the expenditure of 5,000,000 roubles in improving the means of transport of petroleum across the Caucasus, and that 750 new tank cars, 28 Fairlie locomotives, and extensive tank storage at Batoum and other points are at once to be provided. The sum of 3,000,000 roubles is now being spent upon harbour works at Batoum, and it is possible that before long petroleum may be shipped in tank steamers from this port.

The following table, for which I am indebted to Mr. Sacker, gives the distances in Italian miles of

some of the principal petroleum markets of the world from Batoum and New York respectively:—

To.	From Batoum.	From New York.
Alexandria .....	1312	5030
Algiers .....	1978	3586
Amsterdam .....	3347	..
Antwerp .....	3185	3318
Bremen .....	3442	..
Havre .....	2990	..
Genoa .....	1910	1075
Gibraltar .....	1810	..
Hull .....	3242	..
Hamburg .....	3452	3576
Leghorn .....	1855	..
Liverpool .....	3110	3000
Lisbon .....	2121	2980
London .....	3190	3210
Malta .....	1117	..
Marseilles .....	2041	3013
Naples .....	1586	1200
Palermo .....	1507	1115
Smyrna .....	860	1882
Trieste .....	1768	1982
Constantinople .....	582	5260

At the present time practically the whole of the tank storage at Batoum is owned by Mr. Palaschowsky, who has also a factory fitted with all the newest American machinery for turning out 6,000 tins and 3,000 wooden cases per day. I have already referred to this form of package as employed in the shipment of petroleum to hot climates. The cost of the complete case made in Batoum is 92 copecks (less than 2s.), viz., 28 copecks for the wood case and 32 copecks for each tin. American barrels are worth in Batoum about 6s. 6d. and barrels made in Baku cost about 8s.

It is contemplated to provide a third outlet for Baku petroleum by the construction of a railway line from Petrovsk, on the Caspian Sea, to Vladikavkaz. The line would be about 160 miles in length, and its estimated cost is rather more than £1,500,000 sterling. It has also been proposed to connect Novorossisk with Vladikavkaz and Baku with Petrovsk by rail.

The astakki is usually conveyed from Baku to Tsaritsin and other points on the Volga in sailing vessels and barges. When this fuel can be cheaply conveyed to Batoum or Poti it seems likely to compete with coal, of which about 300,000 tons are annually shipped (chiefly from England) to Black Sea Ports.

The two principal routes to Baku are (1) *via* the Black Sea and Transcaucasian Railway, and (2) *via* the Volga and the Caspian Sea. For those who can spare the necessary time, I would strongly recommend from personal experience the following circular tour:—London to St. Petersburg, *via* Hamburg, Copenhagen, Gothenburg, and Stockholm. St. Petersburg to Nijni Novgorod, *via* Moscow. From Nijni Novgorod down the Volga to Astrakhan. Astrakhan by steamer to Baku. Baku to Batoum by Transcaucasian Railway. Batoum to Constantinople by Austrian Lloyd's steamer, touching at Trebizonde and other places of interest, as well as great natural beauty on the coast of Asia Minor. Constantinople to London by the Orient express, or if time permits, home by way of Athens and the Adriatic. This journey is not far short of 8,000 miles in length, without the detour to the Piræus, and occupies about two months, including a reasonable time spent at various places of interest. It may be materially shortened by proceeding overland to St. Petersburg and by taking the rail from Moscow to Tsaritsin, thus cutting off a good deal of the tedious, but in some respects interesting, Volga journey of 1800 miles from Nijni Novgorod to Astrakhan. The Constantinople route home is also by no means the shortest from Batoum, and those who are pressed for time should take the steamer to Odessa. A route which is highly spoken of by those who have traversed it is

from Rostoff-on-the-Don to Vladikavkaz by rail, and thence to Tiflis on the Transcaucasian Railway by road through some of the finest mountain scenery of the Caucasus. The shortest route from London to Baku is *via* Berlin, Odessa, and Batoum. By this route Baku is about 2,500 miles from London, and may be reached in 10 or 12 days without material discomfort or fatigue. As Baku is undeniably a hot place in summer, the visitor should not arrive there before the middle or latter part of September, and if the Volga route be selected Nijni Novgorod may thus be visited on the way to Baku before the closing of the great fair.

#### DISCUSSION.

Professor DEWAR, in thanking Mr. Redwood, called attention to the valuable results to be effected by utilising the volatile portion of the products obtained by distillation, for working gas engines.

Sir F. A. ABEL, in supporting the thanks, spoke of the application of the least volatile petroleum products as fuel for locomotives and steamers, and said he felt perfectly sure that, not only in the mercantile marine, but from the small torpedo vessels to the large men-of-war, where the saving of space was of such great importance, the introduction of liquid fuel would prove a new era in maritime power.

Replying to an inquiry as to the differences between Russian and American petroleum,

Dr. ARMSTRONG said that Russian petroleum was a material of very great interest to the chemist, as there could be little doubt that it was entirely different in composition from American petroleum. The American oil, it is well known, contained little besides hydrocarbons of the methane or  $C_nH_{2n+2}$  series. According to Markovnikoff and Oglobine (*Ann. Chim. Phys.* 1884, [6] 2, 372-484), whose investigations appeared to merit every confidence, the Russian oil contained a very considerable portion of benzenes (pseudocumene, several isomers of cycnene, and also of its next homologue), and of other benzenoid hydrocarbons; it chiefly consists, however, of hydrocarbons of the  $C_nH_{2n}$  series, *isomeric* both with the olefines or true homologues of ethylene, and with the hexhydrides of the benzenes. These latter hydrocarbons exhibit the closest resemblance to the paraffins; but are of higher density than their isologues. They are attacked by chlorine, yielding chlorinated derivatives; but on oxidation are completely destroyed without furnishing characteristic products. The following is a list of the hydrocarbons of this group, which have been separated from the Russian oil:—

B. P.	Density at 0° C.	Density at 0° of isologous normal Paraffin.
$C_8H_{16}$ .....	119	771 grm. per cent. .... 718 Sgrm.
$C_9H_{18}$ .....	131	7808 .. 723 "
$C_{10}H_{20}$ .....	166	795 .. 756 "
$C_{11}H_{22}$ .....	180	819 .. 757 "
$C_{12}H_{24}$ .....	195	8025 .. (at 17°) 7557 "
$C_{13}H_{26}$ .....	210	8190 .. 7653 "
$C_{14}H_{28}$ .....	247	8291 .. —

MR. E. K. MUSPRATT IN THE CHAIR.

## ON INSTRUCTION AND EXAMINATIONS IN CHEMICAL TECHNOLOGY.

BY A. NORMAN TATE.

I THOUGHT it might be well to bring before the members of this Society, for the purpose of opening a discussion, some items that I think should be considered with reference to the future progress of chemical industry. The members of this Society deal with processes based upon scientific facts and principles, and for the successful carrying out of these processes, there is required, not only a knowledge of these facts and principles, but a further knowledge and full appreciation of numerous technical details and practical skill in working these out. Now one of the chief objects of this Society is, or should be, the further development of chemical industries, and therefore, the question may be fairly asked, What is the Society now doing in furthering chemical industrial progress, and what else may be done to supplement present work? In one direction something is being done, and that is in the publication of the *Journal*, which month by month gives important information respecting chemical processes, and the opinions of those engaged in different departments of chemical industry, and thus form a medium of communication between the members that is extremely valuable. I would suggest that we should do something in the way of instructing workmen and others in the several facts and principles on which their work is founded, and training them in practical technical details.

There is very little done in this country, so far as I can see, in actual practical instruction in technology. There are certainly lectures on technology, and certain courses of instruction given in some of the colleges and schools throughout the country, but these courses are too frequently little more than mere lecture instruction, and not to my mind sufficiently practical; therefore, I think this Society may take some steps to encourage more practical instruction bearing upon technical details. Certainly there is much that is extremely valuable in the technological instruction given in Owens College, Manchester; University College, London; The Technical Chair of Chemistry in Anderson's University, Glasgow; and the Finsbury Technical College of the City and Guilds of London Institute, and other places; and the scheme of instruction fostered by this last-named Institution is probably one of the most complete schemes ever put forward, for, although not actually teaching all branches of technology, the Institute's scheme of examination indicates a fine field of technological work for students. But this scheme, admirable as it is, is, as I think, far from perfect, and unless greater care is taken may lead up to, and in many cases end in, the answering by written answers certain printed questions, and many of the questions put are such as can well be answered by a clever crammer, destitute of any really technical skill. I have gone carefully through the questions in several subjects, and consider many of them quite unfitted to test technical knowledge. Many of them are such as may be put to elementary students in science subjects bearing upon the technological subject to which they refer, but they are not calculated to test a knowledge of technical details. Then, again, some of our best

workmen cannot possibly succeed in such examination. A man may be able to work in a most admirable way and know everything necessary for successful work, but not be able to put his ideas into shape so as to properly describe the process on paper, and until we have a better educated race of workmen (and of course we may hope for that now that elementary education is given to all), such paper examinations are useless to a very large number of our most experienced workmen, who, if they attempted the examinations, would be most certainly plucked.

I therefore think this scheme of the City and Guilds of London Institute faulty and incomplete. But I certainly look upon what I consider its faults, as such only as are incidental to new enterprises, and probably useful additions will be made when further experience is gained. I cannot, myself, consider any system of examination in technology complete unless it includes some test of practical work involving actual supervision, for the very essence of instruction in technology seems to me to aim to give power to do work—that is, not only to understand all that is stated in a lesson, but power to work out in practical shape, with attention to all necessary details, that which is described or shown by the teacher.

I cannot help thinking that something may be done to promote sound instruction and examination in chemical technology by the Council of this Society, and I would suggest that it is advisable there should be appointed a permanent committee of the Society, and that the work of this committee should be to first ascertain what is being done in this and other countries in the way of affording facilities for instruction in chemical technology. The Report of the Royal Commission on Technical Instruction, lately issued, would form a most convenient and instructive source from which to give a preliminary report on the present position of chemical technology. Next, the committee might gather opinions and facts from amongst the members and others, as to the value of existing modes of instruction and examination, and make suggestions that would amend or add to them. And again, suggestions may be gleaned and passed round amongst members as to individual effort in promoting more careful study and working out of technological details—as, for instance, in the way of offering prizes to workmen and others who show themselves most fitted to receive them. The Society of Arts now offers prizes for inventions and work of different kinds, and could not this Society do something in this direction also? When the Royal Commission on Technical Instruction was taking evidence, nothing was done by this Society to afford information, but had such a committee as I suggest been in existence, probably much valuable aid might have been given by it.

In conclusion, I would say that I think we have to strive to give more complete technical instruction to workmen and others before they enter works, than is afforded by the lectures and courses of instruction given in our colleges and schools at the present time; and believing that a committee, such as I allude to, could aid much in promoting a better system of instruction, I suggest that this section passes a resolution asking the Council to consider the subject, and if they think fit appoint a committee.

MR. MOSBY said in the early days of the Society this no doubt was one of its objects, but as they had gone on and become more numerous, it had gone into the background. There was a paragraph contained in the original bye-laws which had special reference to the promotion of technical education in chemical industry, but it was omitted in the new bye-laws. It had become a great deal more difficult to deal with any subject of the sort, through

the many sections that had been formed. The consequence was that every step which the Society had to take had to go through the Sections, and opinions taken there; and it was really difficult now to get at the opinion of the Society as a whole, as the yearly meetings are no longer made use of for the purpose of ascertaining the opinion of the Society upon any special subject. His own opinion was that a very great deal was still to be done in the direction of getting technical education, he would rather say scientific education, in England. He would not say of improving it, but he said deliberately, a great deal had to be done in getting it. He certainly personally wished that their Society should do its share, if it could, in this matter. The notions with reference to technical education appeared to be peculiarly mixed up, and he was very much struck with the remarks of Mr. Tate, when he spoke of the young men who went to Owens College and other scientific institutions, and the figure which young working men would make if they had to pass an examination. There seems here to be a confusion between the education which had to be given to workmen and the education which had to be given to men who had to manage works. Surely these two questions should not be mixed up. They were as different as different could be. If it was desirable to give a certain grounding in natural science to working men—men who earn their living by daily wages—this ought to be done by primary schools, by teaching every child in the country a certain small amount of natural science and the general laws which govern the universe. To do more, he, for one, considered impossible. A man who had to earn his livelihood by daily wages could not afford to attend schools the object of which was to teach anything more than what could be taught at the elementary schools. As to teaching technology to men who were to manage works, he was of opinion that as little of it should be taught as possible. There he was at variance with gentlemen who now tried to teach technology. It was absolutely impossible in a school to teach that which was done in works. The only thing they could do was to make him understand the principles which governed what was done in works, by giving a sound scientific education. Whatever else was wanted, he could only learn in practice. He thought the suggestion which Mr. Tate had thrown out was desirable to bring under the notice of the Council. His own opinion was that it was very desirable to make the Society as useful as possible.

The CHAIRMAN must say he agreed to a very great extent, if not with all, that Mr. Mond had stated. The fact was that there was a confusion in the minds of all Englishmen as to what technical instruction was, and what scientific instruction ought to be. They could not expect that they could teach in schools how to carry on chemical operations on a large scale. At the same time he thought that in teaching chemistry in their schools and in their colleges, it might be taught in very different ways by different teachers. Passing a pupil simply through quantitative analysis would not qualify him very well for taking part in chemical works. On the other hand, if the pupil had an opportunity of preparing substances in the laboratory on a somewhat larger scale, and carrying on chemical operations there to a greater extent than they did now, he would learn a great deal more of the behaviour of substances, and he would be more usefully instructed than by the courses hitherto given. People who employed chemists in works, knew that some of them differed very much from others, and that those who had been educated in some laboratories were much better fitted than others for

their duties. All they could do was to teach science, they could not teach technology in schools. He knew that the Technical Institution in London, of the City Guilds, had endeavoured, and he believed were endeavouring, to teach technology. He thought it was a mistake—he used technology in the narrow sense of the word. He thought they would find that they could do very little in that direction, but he hoped they would be able to teach science in a different manner, and they ought to teach it in such a manner as to promote original research both in practical and scientific chemistry. In the course of time, he had no doubt, he should evolve in England some course of instruction which would be suitable for the condition of English manufacturers; but the Germans and some Continental nations who had much longer experience of this question of technical instruction, had, he thought, come to the view which had been enunciated by Mr. Mond, that you practically cannot teach technology in the narrow sense, and the art of carrying out chemical operations on a large scale they could not teach in any school whatever. That experience must be got in the works themselves. This excluded the possibility of carrying out Mr. Tate's desires. At the same time he thought it desirable that this question should be considered by the Society of Chemical Industry; but it was desirable first that they should discuss it in their sections, and if they came to the opinion that it was desirable to have a more general discussion, call the Society's attention to it. The proper way would be to pass a resolution in that section and send it on to the Council, and then it would be fully discussed. The object of the questions in the technological examinations should be to endeavour to find out whether the pupil understood the laws which lay at the basis of all operations in the chemical works. If he did that he would be properly qualified for taking part in chemical works, after he had a certain amount of experience in the works themselves.

Mr. MOND observed that lectures could never do more than give the pupils an idea of the apparatus used and the processes employed. They could not possibly teach how to perform the operations, either to design or use the apparatus. Lectures could only give a general idea of how the thing was generally done. The general idea was exceedingly useful, but it would never enable a man to carry the thing out. They would have to learn it practically in the works themselves. Even when teaching technology, the knowledge which was given was not only imperfect, but it was never up to date. The lecturers on technology could never know, and the text books never contained, the processes actually at work. Usually they were ten years behind the present time, and very often longer than that.

Professor CAMPBELL BROWN was exceedingly glad to have heard the remarks from Mr. Mond, and from the Chairman that evening, because he had long felt there was a great deal of misunderstanding in the popular mind as to what could or ought to be done in the way of technical instruction. The popular idea was that a young man ought to go into a technical college and be taught from the beginning to the end the whole process of making one thing whether soap, alkali, bleach or dye. It was perfectly clear that men did not learn these things without first learning a great many other things, and he was exceedingly glad to hear from Mr. Mond that technical details could only be learnt in the works, and that technical colleges had to do was to teach those who were to go into the chemical works, the laws of nature, and how to observe and report observations correctly. Mr. Tate had remarked upon the system of the City

Guilds Institute. No doubt the examination questions were sometimes very absurd, but they were not more absurd than examinations generally were. He believed it was a fact that examinations would never be able to determine who was the best practical man. They had signally failed to do so in the universities in this country, and probably everywhere else. He believed the system of examinations so enthusiastically carried on at South Kensington, was responsible for a great deal of the mistaken energy which had been devoted to this kind of cramming for science and art examinations. But when they looked away from the examinations, and saw what was being done in the way of teaching, they found a very different account. It was not by examinations, but by the teachers looking over the work from day to day and from week to week, and making a report of what was done, that they could pick out the best boy for practical work. In the ordinary examinations a boy might not be very well on the day he had to write his answers. He had known men who were perfectly capable of becoming senior wranglers that could not pass, because they had the toothache the night before. He was glad the members of the Society were prepared to state their opinion, and whatever the Society did it should be in order to get good preliminary training, to get pupils to observe the laws of nature, and then refer them to the works for technical details.

A discussion took place as to the form the resolution suggested by Mr. Tate should take, but it was ultimately agreed that the discussion should be renewed at a future meeting, when members would have sufficient opportunity of reading the report, or at least the recommendations of the Royal Commission on technical instruction.

UNIVERSITY COLLEGE, ASHTON STREET, LIVERPOOL.

Wednesday Evening, February 4, 1885.

MR. E. K. MUSPRATT IN THE CHAIR.

THE CHAIRMAN stated that he had received a letter from the President of the Society (Dr. Perkin), who was endeavouring to get subscriptions to the Henry Watts Fund. There was enclosed a circular from the Birmingham Section, asking for subscriptions to assist Mr. Watts' widow and children, seeing how much industrial as well as scientific chemistry owed to Mr. Henry Watts. Mr. Muspratt thought they would all agree with him that it was desirable that they should do what they could towards this very worthy object. Mr. Watts did a great deal for chemistry, and his Dictionary of Chemistry was a most valuable work. Perhaps some gentleman would move that the Committee send out invitations to subscribe to the fund.

It was moved by Mr. CAREY, seconded by Mr. A. NORMAN TATE, that the Committee issue a circular, inviting subscriptions to the fund, on behalf of this Section.

The motion was carried.

The discussion on Mr. A. Norman Tate's paper, read November 5, was then reopened by Mr. Watson Smith, who contributed the following paper:—

## ON A COURSE OF INSTRUCTION IN TECHNOLOGICAL CHEMISTRY, AND THE DIFFICULTIES AT PRESENT ENCOUNTERED AND TO BE OVERCOME IN THIS COUNTRY.

BY WATSON SMITH,

Lecturer in Chemical Technology in the Owens College, Manchester.

SINCE the subject of "Instruction and Examinations in Chemical Technology" has already awakened interest and discussion in this Section, Mr. A. Norman Tate having led the way with a communication bearing the above title, in re-opening the adjourned discussion, I may perhaps be excused for giving my views on a subject to me of the greatest interest. Taking the subject of general technical education in the first place, the division of the subject-matter made by the Royal Commissioners in their Report, is a fundamentally necessary one, for it is clear, as pointed out by Mr. Mond, that the kind of instruction needed by the different classes of persons engaged in technical pursuits, must from the very nature of things be different. This division is—

*Firstly*:—The instruction of the proprietors and superior managers engaged in industrial pursuits.

*Secondly*:—That of the foremen engaged therein.

*Thirdly*:—That of the workmen;

and this division applies to the chemical industries as to every other branch of applied science. Commencing at the bottom and referring to the ordinary workman, a very elaborate degree of technical education would be out of the question, inasmuch as the people of the working class have neither time nor money to expend in obtaining it, but for boys belonging to this class, the board schools are already doing an enormous work. I need not, perhaps, remind Liverpool men of the great success which has attended the teaching of the principles of science under the auspices of the Liverpool School Board; but as the method of carrying out this scheme of science instruction may not be generally known, I will not apologise for reading extracts from the Report of the Royal Commissioners on the subject.

LIVERPOOL.

*"System of Science Teaching in Liverpool Board Schools.*—With a view to the provision in the curriculum of their schools, of some subject specially calculated to awaken and exercise the observing faculties of the children, the Liverpool School Board, acting on the advice of several eminent scientific gentlemen, in March, 1877, resolved to introduce the systematic teaching of elementary science into their schools. The branches of instruction were selected from the limited number of science subjects included in the fourth schedule of the New Code of that date, viz., mechanics (or, the principles of natural philosophy) for boys, and domestic economy for girls. The instruction given is necessarily based on the syllabus of each subject set out in the schedule, in order to qualify the scholars to earn grants under the Education Department; but in each case the subject, as arranged in the code, has been modified and extended so as to enable it the more readily to be taught by experimental demonstration to large classes of children.

*"Science Demonstrator in Elementary Schools in Liverpool.*—The method of teaching the subjects, which has been found by experience to be capable of producing very beneficial results to the scholars, is to combine ordinary lessons by the teachers of the school with a system of experimental demonstrations given by means of specially appointed demonstrators. The apparatus required for the demonstrations is kept at a central laboratory, and is transferred from school to school, as

required, by means of a light hand-cart. In this way each demonstrator is able to give from 15 to 20 demonstrations per week. In order to simplify the arrangements for the demonstrations as much as possible, by providing for the same demonstration to be given in several schools in succession, the Education Department was, at the commencement of the scheme, requested to provide for the school-years of the different schools to end as nearly as possible at the same time; and this was carried out so far as to admit of the schools being arranged in two groups, the annual examinations of which fall in the autumn and spring respectively. In the case of domestic economy, the demonstrations are given only every alternate week, and the same is the case in the second stage of mechanics (taken by the Fifth Standard), but to the Fourth Standard, just commencing the subject of mechanics, one demonstration is given every week. In the intervals between the demonstrations, the teachers of the respective classes, who are supposed to be present at the demonstrations, are expected to go over with the children the subject of the demonstration; and in many instances their lessons are illustrated by simple experiments; and in order to enable the teachers (the larger number of whom have unfortunately had no special training for the subject) to perform their portion of the work more satisfactorily, a simple text-book has been specially prepared, containing reading lessons on the subjects of the demonstrations, and exercises to be worked by the scholars. The demonstrations have been given in several of the other elementary schools of the town, not under the Board, on payment by the managers of the schools, of a proportion of the expenses.

At the present time there is one chief demonstrator, who has also to organise the instruction, and two assistants.

The cost of the apparatus used in the school demonstrations for the five years during which the scheme has been in operation amounts to about £120, many of the articles having been provided in duplicate in consequence of the large number of classes.

*Science Tuition of Pupil Teachers in Liverpool.*—In addition to the instruction given to the scholars, special science classes in connection with the Science and Art Department, have been arranged for the pupil teachers, so as to gradually train them to take an intelligent part in the work in the schools. About 70 male pupil teachers attend the central classes in mathematics, acoustics, light and heat, and electricity and magnetism; and about 100 female pupil teachers are under instruction in animal physiology. A short course of lessons in mechanics is also given each year to the male pupil teachers.

*Liverpool Council of Education.*—Mr. Christopher Bashiell explained to us the action of the Liverpool Council of Education, a body of which he is the president. The object of the Council is to connect the Elementary Schools in the city with the Secondary Schools. For this purpose a system of prizes and exhibitions has been established, and independent examiners report on the quality of the papers which are set by them, and the Council acts on this report in their selection of the candidate. From the Secondary Schools the boys obtain an opportunity of passing to the higher colleges or to the Universities of Cambridge and Oxford.

*Evening Science Instruction in Liverpool.*—A very important feature in the educational institutions in Liverpool, is the systematic series of evening science classes. There are two distinct organisations founded for this purpose, each of which carries on classes under the Department of Science and Art, without interfering with the other. They act as friendly rivals, and the result is that, probably, in no city in the kingdom are these classes more flourishing, or doing better work than in Liverpool. One of these organisations is termed the 'Liverpool School of Science,' the other 'The Liverpool Science and Art Classes.'

#### MANCHESTER.

*Elementary Instruction of the Manchester School Board.*—The Commissioners inspected many of the

schools under the direction of the School Board of the city of Manchester. The average attendance in this city for the quarter ending September, 1883, was: Voluntary schools, 25,736; and board schools, 19,992; or 1 in every 7.5 of the population, and the cost to the ratepayers during the last five years has been 2d. in the £. Statistics of the School Board and particulars of the visits paid to the schools will be found in the Appendix, Vol. IV.

*Manchester Higher Elementary Schools.*—*Science Teaching and Evening Classes, under School Board.*—*Manual Work.*—The points of special interest as regards technical instruction are: (1) The foundation by the Board of so-called graded schools, or higher elementary schools, into which the more advanced or most talented children from the primary school can be drafted, and where the higher subjects, especially science and drawing, are taught more satisfactorily and more economically than can be done in a school containing children of all ages and of all stages of progress; (2) The establishment by the Board of a systematic series of science and art evening classes, as well as of evening schools, for providing instruction in reading, writing, and arithmetic, for those who have had no opportunity of learning when young; (3) The establishment of classes for instruction in the use of tools, in two of the Manchester Board Schools.

*Central School.*—Of the higher elementary schools two may serve as examples. The first and most remarkable of these is the Central School in Peter Street, taken over by the Board in 1883, and now transferred to new and most complete premises in Deansgate. The results of the science teaching in this school are well worthy of notice. Out of a total of 320 boys, 276 have passed Standard VI., and are taught during the day mathematics, physics, chemistry (both practical and theoretical), sound, light and heat, magnetism and electricity, physical geography, and mechanics. French, too, is taught throughout the school. A girl's higher elementary school forms one-half of the building.

*Practical Chemistry.*—The total grant from the Science and Art Department earned by this school in 1882-3 was £398. Practical chemistry is extremely well taught; no less than 163 boys, of whom 28 are advanced pupils, were engaged in laboratory work in the winter 1883-4, as well as 20 girls, and the new school buildings in Deansgate contain a laboratory well fitted and arranged for 70 boys working at once, with a lecture room attached seating 100. Every boy in the school learns drawing upon the South Kensington method.

*Scholarships.*—To the boys' school is attached one for 200 girls, and 20 scholarships exist for necessitous boys and girls from the primary schools. These are of the greatest service, as they form the first step in the ladder by which a talented boy may climb from the board school to the University. Other scholarships take the boy from this higher elementary to the Manchester Grammar School, and others again from that to the University. Several boys have already accomplished this feat.

*Ducie Avenue School, Manchester.*—The other higher elementary school visited is that in Ducie Avenue. This is a new school containing 900 children in four departments; it cost, with land, fittings, and chemical laboratory, about £11,000. The upper school fee is 9d. per week, the lower 6d. and 4d. Both boys and girls are taught science, and both—viz., 69 boys and 46 girls, work in the chemical laboratory, which is in a separate building, well lighted and ventilated, and having a special class-room attached; of the boys, 136 are in Standards VI. and VII., or above, and of the girls, 96. The grants earned by this school from the Science and Art Department were £112; and this, together with the school pence, more than cover its working expenses.

These two schools may be taken as an example of what can be accomplished by the School Board in a large city, even with as low a rate as 2d. in the £; and although in appliances of certain kinds these schools are less completely furnished than many Continental schools, your Commissioners have seen none which sur-

passed them in general efficiency, or in the tuition of any special subject, except in that of drawing."

#### BIRMINGHAM.

"*Birmingham School Board, Science Instruction.*—On the occasion of their visit to Birmingham, the Commissioners met the members of the School Board, and inquired into the system of science and art teaching under the Board.

"*Board School Instruction in Elementary Science.*—Science is taught in accordance with the following syllabus, by a practical demonstrator and assistant (who visit each boys' and girls' department once every fortnight), and by the teacher of the school.

"*Method of Instruction.*—The science demonstrator for the Board (or an assistant demonstrator) gives one lesson fortnightly, of about 40 minutes' duration, to the boys in the fifth and higher standards in each school. These lessons are illustrated experimentally by specimens and apparatus, carried from school to school in a hand-cart.

"Between the visits of the science demonstrator at least one lesson is given to the same class by the teachers of the respective schools (as a rule by a teacher who was present at the demonstrator's lesson, and took full notes of it), and a written examination on the subject-matter of the lesson is also held. The answers are corrected by the class teacher, and submitted to the demonstrator at his next visit to the school. A general examination in elementary science is held yearly.

"*Syllabus of Fortnightly Demonstrations for Boys.*—Specification of a force; nature and action of machines; principle of work. The mechanical powers; conditions of equilibrium; the mechanical advantage; friction. The lever; parts of a lever; three orders of levers. Practical applications of the lever; double levers. Weighing machines; the balance; the steel-yard. The wheel and axle; practical applications of this machine. The toothed wheel; clocks and watches. The pulley; fixed and movable pulleys; the three systems of pulleys. The inclined plane; its principle and applications. The wedge. The screw. Compound machines. Pressure of liquids; surface of liquids; liquids under the action of gravity. The hydrostatic press. The parallelogram of forces. The parallelogram of velocities.

"*Syllabus of Fortnightly Demonstrations for Girls.*—Structure of the human body; names and positions of the various organs; structure of the skin; the teeth. Circulation and respiration; impure air and ventilation. The organs of digestion; the brain and nervous system. Nature of food; necessity for food; quantity required; classification of food. Preparation of food; meat: its composition and culinary treatment. Fish, eggs, milk, butter, cheese: Principles regulating their use and preparation as food. Flour, pulse, peas, beans: their composition and preparation for the table. Starch, sugar, fruits, vegetables: their use as food. Condiments and beverages. Apparatus for cooking; how used. How to maintain the body in health: I. Fresh air and pure water are needful. II. A suitable dwelling, sufficient food, and exercise (work) are also required. The sick room: duties of a nurse. Contagious diseases: their origin and treatment. How to prevent them spreading. Diseases of children: how to help the doctor. Accidents: what to do in cases of cuts, burns, &c.

"*Science Evening Classes under School Board, Birmingham.*—Classes for the evening instruction of pupil teachers are held at two centres, under the regulations of the Science and Art Department. Male pupil teachers take chemistry and magnetism and electricity; and females, physical geography and magnetism and electricity.

"The Commissioners visited the Icknield Street Board School, which has been provided with an excellent laboratory, in accordance with the requirements of the Science Directory. Here some of the senior boys and the pupil teachers have practical laboratory instruction in chemistry.

"Instruction in handicrafts is not as yet given in any of the Birmingham Board Schools, but this matter is under the consideration of the Board."

Thus we see that for those working men having a real love and aptitude for the pursuit of science the evening classes of the Science and Art Department offer ample opportunities, and the abler boys from the primary schools can pass by exhibitions to the higher institutions in the town. *This connection between the higher board schools and the colleges, and even universities, is one which ought to be much extended, and on this point I desire to lay the greatest stress.* In this country, it can at present only be established by the voluntary movement of generous hearts and open hands. On the Continent, in Germany, it follows as an establishment of law, effected by so-called paternal governments, albeit both wise and far-sighted.

The Foremen are usually chosen in our industries, as indeed the name indicates, from the best workmen, and so the education would be much the same as that for the men, and here other characteristics also would come in, helping to raise the men to this next step higher, that of foremen, as conscientiousness, presence, and power of command, physical strength, etc., which certainly do not form subjects for either examination practically or on paper. But still, those of these men who are the best, and have taken fullest advantage of their opportunities, are the ones that must in the end best succeed. That this feeling has now become a common one, is borne witness to by the fact of such large numbers of candidates for instruction in the great centres of industry. Amongst the other means now accessible to the poorest of our countrymen are the evening classes under the Science and Art Department, in which purely scientific tuition is obtained, and most wisely and excellently engrafted on to this is the scheme of the City and Guilds of London Institute for encouraging more specialised knowledge, perhaps we might or ought, I think, to be able to which define as *scientific instruction with a bias in certain directions—viz., the Technological directions.* The bias is involved, of course, in the application of the science to the *modus operandi* and means adopted, for the realisation by utilising certain of its laws and facts, of produce on a large scale, a larger one for example, than that of the instruction workshop or laboratory. As regards the chemical industries, there is analogy then between the laboratory and the works, and since the proper construction and use of apparatus in the laboratory forms a phase of instruction inseparable from the learning of practical scientific chemistry, so in the case of chemical work on the large scale, the general principles of construction and use of plant and apparatus, must also form a phase of instruction inseparable from the learning of practical chemistry as carried on in the works. I am quite aware that other prominent conditions come in, in the latter branch, and are important, as economics, wear and tear, etc., matters based on long observation and experience, and for all these reasons, it must be plain that only a certain amount, and that not a very large one, can be taught in schools and colleges, of this subject of Technical Chemistry in the full sense. It is a subject for a life practice; but I hold most firmly, as I know by experience, that a certain amount can be taught and usefully taught, and further, that much more can be taught by those who have had at one time or another actual living experience in the works, just as practical and analytical chemistry can be taught best by those who have worked themselves in the laboratory, rather than by those with a mere book-knowledge of the methods used.

As to practical technical skill conferred by knowledge of general scientific principles amongst workmen and foremen, this might not be very specially manifested in some mere rule-of-thumb processes,

supposing the workmen "were watched at their work"; the result of such instruction and training will be a general improvement, but nevertheless the "power to do work" must be conferred, for is not knowledge power, and power to do work? If, moreover, an objection to the examination scheme of the City and Guilds of London Institute is, that a large number of our present most experienced workmen are unable to express themselves in writing so as to give replies to the questions, we now see from what I have read from the Report of the Royal Commissioners, that the growing generation will not have that difficulty to contend with, and so the Institute will soon outgrow this defect, if it be one. I consider that the examination questions "such as may be put to elementary students in science, bearing upon the technological subject to which they refer, *without testing* the knowledge of technical details," if understood and answered, might be evidence of great good being done, and of a kind, were I the employer of the successful examinees. I should hail with delight; but to draw forth in public examination form from my workmen evidence on paper of a knowledge of technical details in some directions might excite my feelings in quite another direction. These details belong essentially to the works, and the teaching of applied science in the wide and true sense can flourish without them, *for it aims at growth of understanding, reason and intellect*, and not at accumulation of knowledge of special details.

References were made, not very favourably, in the November discussion to science examinations generally, and to those of the South Kensington or Science and Art Department especially, and the well-worn objection of so-called "cramming" was brought against them. It must be remembered, however, that the word *cram* can be only too easily applied. The mind cannot be stored with facts, without these facts being introduced somehow, and the substitution of the word *cram* for *introduce* is often too lightly made. Examinations must be passed, just as competition in business must arise, and just as races must be run in many ways, and in many spheres of work. Such competition is considered a healthy sign. But as regards this alleged "cramming" for Science and Art examinations at South Kensington let us remember some important statements on this head, by no less an authority than Professor Huxley, to wit, that when he looks back at the state of scientific ignorance in this country some thirty years ago, and then regards the present state of comparative enlightenment, he is astonished at the advance, an advance largely due to the effect of the study, reading and work in preparation for the continually recurring examinations of the Science and Art Department.

Now with regard to the first group referred to in the Royal Commissioners' Report—viz., the *Proprietors and Superior Managers*, and their instruction in Chemical Technology and the attendant or involved branches of science. You will have already read in the address of Sir Henry Roscoe at the opening meeting of the Manchester Section, in the number of our Journal for last December, what his views are on the subject of the higher education and training needed by this class, all of which I most cordially endorse. Especially would I call attention to Sir Henry's weighty words on page 594 (paragraph at foot of column one and top of column two), where he points to the highest platform, or school, needed by those who are to be our leaders in industrial science,—viz., that of *original research*, the search after new manifestations of laws and forces, or even after new laws and forces, for only by such search can the closest intimacy of acquaintance with the workings of these laws and forces be attained. Then as regards the wider general educa-

tion necessary for this class, I would refer to the important words in Vol. I. of Rep. Roy. Com., pp. 515 and 516.

#### "Technical Instruction for Proprietors and Managers.

—In determining what is the best preparation for the industrial career of those who may expect to occupy the highest positions, it is necessary to differentiate between capitalists who will take the general, as distinguished from the technical, direction of large establishments, and those at the head of small undertakings, or the persons more especially charged with the technical details of either. For the education of the former, ample time is available, and they have the choice between several of our modernised grammar schools, to be followed by attendance at the various colleges in which science teaching is made an essential feature, or the great public schools and universities; provided that, in these latter, science and modern languages should take a more prominent place. Either of these methods may furnish an appropriate education for those persons to whom such general cultivation as will prepare them to deal with questions of administration is of greater value than an intimate acquaintance with technical details. It is different in regard to the smaller manufacturers and to the practical managers of works. In their case, sound knowledge of scientific principles has to be combined with the practical training of the factory, and, therefore, the time which can be appropriated to the former, that is, to theoretical instruction, will generally be more limited.

*How Training may be Obtained.*—How this combination is to be carried out will vary with the trade and with the circumstances of the individual. In those cases in which theoretical knowledge and scientific training are of pre-eminent importance, as in the case of the manufacturer of fine chemicals, or in that of the metallurgical chemist, or the electrical engineer, the higher technical education may with advantage be extended to the age of 21 or 22. In the cases, however, of those who are to be, for example, managers of chemical works in which complex machinery is used, or managers of rolling mills, or mechanical engineers, where early and prolonged workshop experience is all-important, the theoretical training should be completed at not later than 19 years of age, when the works must be entered, and the scientific education carried further by private study, or by such other means as do not interfere with the practical work of their callings. Many colleges of the class to which we have referred have already arranged their courses to meet these requirements, and some of them, as will appear from our reports of visits, have workshops for the purpose of familiarising the students with the use of machine and hand tools.

Of course Sir Henry Roscoe in his address to the Manchester Section (*loc. cit.*) referred to our course of instruction in Chemical Technology in the Owens College in the examples given, and as it is in this course that my experience is mainly wrapped up, I may perhaps be excused if I refer to some details in connection therewith, which may be of interest and, peradventure, possess some points of novelty.

Although in many respects similar to, and to some extent planned from, the Polytechnikum course followed in Zurich, which curriculum I became familiar with after working there for three years as a teacher as well as a learner, an entirely new departure has been taken in our case having no parallel anywhere that I know of. This is, as I will as briefly as possible try to show, in the intimate and most advantageous connection established between the science degree course of the Victoria University and the course of Technological Chemistry.

It is possible for a student to set out for a four years' study at the Owens College, to make the preliminary course preceding matriculation in the University identical with and cover the preparatory

year for the Technological Chemistry course, and at the end of the succeeding three years to conclude by passing the B.Sc. degree of the Victoria University with honours in Chemical Technology, and also to acquire the certificate (analogous to the Zürich Polytechnikum Diplom) in Chemical Technology. The advantages, to such a student are manifest. He leaves the college armed with the requisite knowledge for starting in life, either in the profession of teaching or in the technical direction, and he has credentials to smooth his way, and to help in opening up whichever path he may choose. If in addition to this the student could take the certificate of the City and Guilds of London Institute, that would be still further proof of fitness. But this requires time, and so did apprenticeships in older times—apprenticeships of seven years for learning a trade. Now let us see what the Owens College course in Chemical Technology involves, and mainly consists of. We have the *Preparatory course*, analogous to the Zürich Vorkurs in which no technology at all appears, for we assume that if we mean by Chemical Technology, Applied Chemistry, then there must be first present the *something to apply* before we can talk of its applications. Hence this first year is devoted to the Study of Inorganic Chemistry (the non-metals), Practical Chemistry (qualitative analytical work in the laboratory, with Analytical Chemistry lectures), Mathematics, Mechanics (lectures), Geology (stratigraphical), French or German, Geometrical Drawing lectures, Mechanical Drawing, practical.

In the *second year*, or *first of the Technological Course proper*, we have Chemistry lectures (non-metals and metals, or junior and senior), Chemical Laboratory (quantitative work), Technological Chemistry lectures (first course). Experimental Physics or Elementary Mineralogy, German or French, with the injunction that it is desirable the student by the end of the second year should have gained a knowledge of the elements of both these languages. Then come Geometrical and Mechanical Drawing lectures and practise, as in the previous year.

In the *third year*, the *second of the Technological Course*, the Senior Chemistry lectures are repeated, if desired. The Organic Chemistry lectures are now entered, with those on Chemical Philosophy. Moreover, as a practical course, the Physical Laboratory is also entered where the practical study of Chemical Physics is pursued, or as a matter of choice the Advanced Mineralogy lectures with a practical course in that branch may be entered. Mechanical Drawing is continued, but now without the Geometrical Drawing lectures, and it is continued to the end of the entire course, so important is it considered that this part of an engineer's training shall be undergone by the students of Applied Chemistry. The second course of lectures in Chemical Technology is lastly to be heard and to be passed.

The final year is devoted to the hearing and passing the lectures and examinations in Organic Chemistry a second time, unless they have been heard and passed in the former year. The Technological Chemistry lectures, two courses—viz., the third and fourth. Chemical Laboratory, four days per week, and Mechanical Drawing. But now you may desire to know what the Technological Chemistry lectures themselves treat of, and how they are graduated to the increasing proficiency in general scientific, specially chemical, knowledge of the student, moreover, what is done in the Chemical Laboratory? We saw that in the *First Year's Technological Course*, the Inorganic Chemistry lectures had already been heard, and now we have a course of applied Inorganic Chemistry, that of the sulphuric acid and alkali manufacture with the attendant

branches, as much as there is time for. It should be stated that these courses are ended by visits to chemical works as far as possible, so that practical illustration of the principles involved in the courses of lectures are thus afforded. In this direction we number amongst our friends of the Liverpool Section, several, who give us annually most generous assistance by throwing open their works to our students, and who generally themselves explain the principles of their plant and processes to them.

In the *second Technological Year*, Organic Chemistry is just commenced, and some insight has already been obtained into it, in the closing lectures of the Senior Systematic course, and moreover the elements of Chemical Physics have also been learned, and now comes a branch of applied Chemical Physics with elementary Organic Chemistry, in the Technological Chemistry lectures, which are heard in this year. A. The destructive distillation of wood and the products obtained. B. The Chemical Technology of fuel, manufacture of coke with recovery of volatile products in coke ovens. C. The distillation of coal-tar, and separation of crude tar products, and ammonia and ammonium salts from gas-liquor.

In the third and final year a further demand is made upon the knowledge of Organic Chemistry, which should now be attained, in the third course of Technological lectures, on the manufacture of coal-tar products, intermediate derivatives and coal-tar dyes and colouring matters; and in the fourth course of lectures, both the knowledge of Organic Chemistry and that of Geometrical and Mechanical Drawing will appear in their full value, in the study of textile fibres, bleaching, dyeing and calico-printing.

As regards the laboratory courses, what is first insisted on is the mastery of systematic courses of qualitative and quantitative chemical analysis, and this before any serious attempt is made in the direction of preparations further than those afterwards employed for analysis. Now it will be said by some, a course of good preparations, or of experimental investigation into the working of fundamental chemical and physical laws, would be of more real service to a student who is to be a thinker, and an original thinker, than all these disciplinary courses of analytical work, already so "cut and dried," and tabulated. I would reply, "there is a time for everything," and after this course of manipulative analytical study is over, is the right time to commence to utilise all the means now acquired and at hand, for original research and investigation, either by means of preparations or original work.

But now to come to one of the difficulties with which such a high standard and course in England is encompassed; this is that its necessity is not sufficiently understood, and yet, so far as I have observed, all those who *have* persevered and *have* passed our full course, are now in good positions, positions proportionately higher to their superior merit.

There is no outlay of proportionately meagre amounts in any commercial branch, for which such, I would almost say, outrageously large and quick returns are demanded, as in Chemical Education in this country.

There is another difficulty, as regards getting admittance for the higher talent of our lower classes into the higher colleges.

However, we are looking forwards hopefully to lay the foundation of a grand system, and the outlook is a satisfactory one, but would be more so if we could only by means of bursaries or scholarships connect the board schools and the higher colleges. When such connection is effected, I should not be surprised to find that in the future, looking at the thoroughness of the teaching given, the managers and even heads of our industrial

concerns will be rather supplied from the chosen spirits of board schools, than from the sons of the wealthier classes who have been sent to Eton and Harrow, etc.

In conclusion, it is pretty clear that the meaning of the word Chemical Technology receives often different interpretations, but the sense in which I have wished to use it and understand it, is to refer to the scientific principles involved in and encompassing the chemical industries, and in the use of means and appliances therein. I know it is nonsense to attempt to teach Chemical Technology, in the narrower sense, in colleges, but there is much that can be taught as already shown, and if the governing principles are taught by those who have lived and served in the factories, more vivid and true pictures and illustrations can be given, and the applications of the principles themselves better amplified and enforced. Nevertheless, so far as my own teaching is concerned, and especially in the branches in which I have had practical experience, it is certainly not behind the times. To be ten years behind, except in certain special branches, limited in number, would argue practical inexperience or negligence, or at all events that our Journal was not serving its purpose in educational directions. I quite agree that the technical text-books are mostly ten years behind, and often more. However, in teaching what I understand by Chemical Technology, it is not necessary to give all that is done absolutely up to date, nor to give full instruction in all that is done. The student's time is far too precious for the latter and too much occupied by the study of broad scientific truths; but the teachers would, or ought to, know how best to give the general outlines, and draw general lessons of scientific principle from what they have seen and know, so that the clothing with more minute practical details, proportions, and quantities would soon be put on hereafter, when the arena of actual working practice is entered. The mental training in generalising legitimately and logically from the smaller area of the laboratory to the larger spheres of working on a larger scale, if it be but by outline and on broad principles, properly carried out, is, I am certain, of the highest value to the student, in furnishing him with general maxims and data to help in clearing his way, assisting his vision and reasoning faculties, and giving him a readiness more quickly to adapt himself at the outset, on entering the works, to the new circumstances and scenes about him. This means, of course, to begin to be of real use to his employers in the shortest possible time after entering their service.

To turn finally to another point which has been mooted. Before the Society of Chemical Industry undertakes to do something to promote sound instruction and examinations in chemical technology, I should like to hear precise definitions of what these are to mean. Our Society, I take it, is doing pretty well in issuing an annual report of the advance of Chemical Technology in the shape of the Journal, which costs many of the members both of our council and the publication committee no little trouble and time. Our Journal is an ever progressing and progressive course of Chemical Technology itself, and both as a standard of the knowledge required, and as a means of instruction, it aims at doing a grand work, in which all its sections and each individual may participate.

#### DISCUSSION.

The CHAIRMAN was sure they were all very much indebted to Mr. Watson Smith for his admirable paper, and for bringing the whole subject so ably before them.

Mr. HENRY BRUNNER: It seems to me that this question of scientific and technical education is a

very large one, more especially as for every different part of our country the system of teaching, and certainly the direction of that teaching, cannot be the same. I think that science, even the most elementary, to be properly taught, ought to be taught by scientific men, and I object very much to this additional work being put upon teachers, such as school board teachers, because they have, as a rule, already too many subjects to teach, and to expect them to take science in addition would be a great mistake. With regard to what Mr. Watson Smith has said about The Victoria University and The Owens College, I am of opinion that they begin too young. A four years' course is very good, and ought to be ample if a student is sufficiently well prepared when he comes there to profit by it, but boys are admitted to the college, and they may commence this four years' course at fourteen years of age. I think that is two years too soon, and that they ought not to be admitted before they are sixteen years of age, because I do not think it possible for boys to take proper advantage of a comparatively severe course of scientific teaching at a time of life when their physical development requires so much care and attention. It seems to me we want something intermediate between our elementary schools and our scientific and technical schools such as The Owens College. What these schools are to be I do not know,\* and from what little I have seen of the Blue Book containing the Report of the Royal Commission, there does not appear to be any suggestion for provision of schools of the kind, but it appears to be contemplated that boys should go from board schools—by which I understand elementary schools to be meant—to scientific and technical schools, and thence, perhaps, pass on to the universities. I want again to say that we are too anxious—or appear to be too anxious—to turn our young fellows of scientific and technical training out into the world too soon. When a young man has finished a course such as that provided by the Owens College, he ought to be able at once to take up in a manufactory or works a position where his knowledge would be of use to himself and to his employers. But at eighteen years of age he could not be put in charge of workmen simply on account of his youth. They would not listen to him. If a student finished his course at twenty or twenty-one it would be quite early enough.

Mr. CAREY: I quite agree with what my friend Mr. Brunner has been saying as to the age of the boys when they begin this technical education. It is too early to take them immediately from the schools, and to, for instance, The Owens College, without distinguishing as to the class in which these boys are, and the future place they are to fill. We have to observe the distinctions which Mr. Watson Smith has spoken of, and which are also spoken of in the Report of the Commissioners—that is, the "workman and foreman" class, and the "manager and employer" class. It is quite obvious that there would be a very much wider education given in the latter case than could be possibly finished by a boy of 16 or 17 years of age. I think the remarks of the Commissioners on page 516, vol. i., bear out what Mr. Brunner has been saying. They say:—

"The best preparation for technical study is a good modern secondary school of the type of the Manchester Grammar School, the Bedford Modern School, etc. We consider it to be essential that steps should be taken to ensure that this work shall be carried on with greater vigour in the future than it has been hitherto. In the schemes for the new schools,

\* But I trust the necessity of physical training will not be so completely overlooked as it has been in our elementary school system.

the subjects of science and modern languages should form a very prominent part. But the existing endowments are unevenly distributed. In many of the large manufacturing centres no resources of the kind exist. Private enterprise is clearly inadequate to do all that is required in establishing such schools, and we must look to some public measure to supply this—the greatest defect of our educational system," etc., etc.

Referring to the subject generally, I would like to say that, with regard to Mr. Tate's paper, I do not agree with all his remarks. I think Mr. Tate proposes, if I understand him rightly, that we should give a detailed technical education to workmen, and to tell them, for instance, how to work furnaces, an education which can only be carried out, I think, satisfactorily in the works. With regard to the preparation for technical work, I agreed with Mr. Moud at the last meeting, when he said something to the effect that we should arrange matters so as to give a student a thorough scientific education, educating his faculties and then leaving the detailed technical work to the time when he gets into actual practical work in the factories. I think you cannot give a young man too wide an education, or one too thorough in actual science, but of course the direction which his scientific studies take must be with a view to the future, and the branch of technology he intends to pursue. I think it might be useful for us, as another text for our discussion, if we took the recommendations of the Royal Commission, and what they suggest should be done in the way of altering our present legislation for the purpose of improving technical education. I do not know whether it would be in order, sir, to discuss these recommendations one by one, to see if we can come to any action upon them, and whether we as a section are inclined to support them, or whether we have any suggestions to make in addition to the recommendations of the Commissioners, both with regard to elementary schools, and with regard to the higher education also. I do not know whether it would be in order now.

The CHAIRMAN: It is in order; and the only question is whether we should come to a definite resolution on the subject, from this Section. I do not know whether it would not be desirable, after discussing the question, that we should not possibly pass some resolution, because I presume if that were forwarded to the proper quarter, it would be some support to the recommendations of the Commission.

Mr. CAREY then proceeded to read as follows:—  
On page 517, vol. I., the Commissioners say:—

"For the great mass of our working population who must necessarily begin to earn their livelihood at an early age, and from whom our foremen will be mostly selected, it is essential that instruction in the rudiments of the sciences bearing upon industry should form a part of the curriculum of the elementary schools."

On page 536 *et seq.* of the same volume, appear the general recommendations of the Commissioners, many of which appear to me to be of great importance—*e.g.*:—

"I. As to public elementary schools.—(a) That rudimentary drawing be incorporated with writing as a single elementary subject, and that instruction in elementary drawing be continued throughout the standards, etc. (b) That there be only two class subjects instead of three in the lower division of elementary schools, and that the object lessons for teaching elementary science shall include the subject of geography."

"II. (a) That School Boards have power to establish, conduct, and contribute to the maintenance of classes for young persons and adults (being artisans) under the Science and Art Department. That in localities having no School Board the local authority have analogous powers . . . .

"V. (a) That ratepayers have power by vote to sanction the increase of the expenditure, under the Public Libraries Acts, beyond its present limit, and that the restriction of the Acts to localities having 5000 inhabitants and upwards be repealed."

In addition to the recommendations which necessitate action on the part of the legislature, or of the public authorities, there are suggestions made for the consideration of those in whose power it is to comply with them, such as:—

"I. That it be a condition by employers of young persons, and by the trade organisations, in the case of industries for which an acquaintance with science or art is desirable, that such young persons requiring it receive instruction therein, either in schools attached to works or groups of works, or in such classes as may be available; the employers and trade organisation, in the latter case, contributing to the maintenance of such classes."

The recommendations which I have read—and they are only examples of many others of equal interest and importance made by the Commissioners—appear to me to give subject matter for serious consideration and discussion, and to be in the main recommendations which should be supported by our Society.

Mr. A. NORMAN TATE said that in opening the discussion at the November meeting, his object was more especially to call attention to the matter, with the view of moving a resolution that that Section should ask the Council to appoint a permanent committee, to take cognisance of what was now being done in this country to further instruction and examination in chemical technology, and to suggest from time to time improvements; and he thought the remarks that had been made that evening, especially those which had fallen from Mr. Carey, showed that such a course of procedure was desirable. He thought he might have been a little misunderstood in the remarks he had made at the November meeting. He certainly did not think it was possible by any systematic course of instruction in schools or colleges to teach workmen or foremen, employers or superintendents of works, all the technical details of any manufacture in which these persons might be engaged, but he did think they might go much further than at present in giving the power to carry on technical work. What was required first of all was a knowledge of facts, and he thought it was desirable to supplement the mere lecture instruction by a course which would bring out the power of observation to a greater degree. Mr. Watson Smith had spoken of the work done by the several instructors in the Liverpool, Manchester, and other Board Schools. He (Mr. Tate) had on two or three occasions had the pleasure of watching Mr. Hewitt, Chief Science Instructor to the Liverpool School Board, in his work of instruction in mechanics, and he put the elder boys through a course of instruction which could not fail to give them powers of observation which they could never have imparted to them by the study of the ordinary subjects of board school instruction. A boy after passing through such a course, if he went into a shipbuilding yard, a builder's yard, or workshop, would have implanted in his mind a knowledge of the principles of much of the work he would have afterwards to carry on. This was the sort of thing that they wanted carried on to a greater extent. Although this work was done in Liverpool, in Manchester, and in Birmingham, if they took other towns where there was a large number of workmen engaged in trades and manufacturing operations, they would find that the lads there left school and went into these manufactories without any such training. If a committee were appointed, one thing that could be done would be to issue recommendations to school boards in towns in which chemical industries were carried on, and point out what was done in other places, and keep them well informed of what was really useful in special technological directions. Then when they came to special studies, he noticed in the Blue Book a very excellent plan of training adopted in certain schools on the Continent. The elder pupils

were occupied some portion of each day in taking meteorological observations. Certain of them were set apart to take the temperature and barometrical pressure, etc., registering these in a careful manner. Now here pupils were trained in powers of observation, and what observations they made could be readily checked. This was one way in which the observing powers might be trained; and there were many others involving the working of simple processes only. A youth going into a chemical works, already trained to take temperature, specific gravity, etc., would often be more useful than the lads who now commence work in chemical manufactories and other industrial establishments. Another point to which he would call attention was, how far it might be desirable to introduce into this country, special schools, something similar to the apprentice schools that are in existence on the Continent. In vol. i. page 48, of the Commissioners' Report, there was a description given of these technical apprenticeship schools. There was much to be said in favour of such schools, either as taking the place of some of the apprenticeships which were in vogue in this country, or in supplementing them. In many of the technological colleges there was a want of grouping, especially in relation to chemical technology. It was all very well to give a student a knowledge of the general facts of chemistry, and of chemical analysis and power to make chemical analyses, and do other laboratory work; but there was wanted something more than chemical instruction, before chemistry could be made available for technological purposes. The student must have a knowledge of subsidiary subjects. How was it that so many of their chemical patents fell through? It was simply through a want of knowledge of the composition of the materials used in carrying out chemical operations and methods of putting them together. Therefore in addition to the knowledge of chemistry it should be insisted upon as a matter of chemical technology, that there should be a thorough knowledge of the building and other materials used, their quality and strength, and the manner in which they could be best utilised for certain purposes. Then again they should have a knowledge of mechanics and machinery. The most elaborate machinery might be designed and yet break down in chemical operations. He therefore could not look upon any course of instruction of chemical technology as complete, unless the student was compelled to study these subsidiary matters to a considerable extent of detail. He did not think that it was altogether impossible, in addition to ordinary laboratory work, that instruction in working experimental furnaces and other larger apparatus used in manufactories, might be given in good technical schools, and certain processes taught, such as, for example, modes of using to best advantage fuel, etc. Industrial museums would, he thought, prove highly useful, and it was to be hoped that the exhibition of inventions, etc., which was to take place next year in London would give them a considerable amount of information. They might do something towards establishing, in the centres of industry, technical museums. A technical museum, in a town like Widnes, would have a very good effect. It would show those who were growing up to enter the works what the substances used and products were that were manufactured in the town, and give them some idea of the general processes by which they were manufactured, and similar museums might be established throughout the country. It had been suggested that in Liverpool there should be a museum of casts; but at a meeting he had attended, when several artisans were present, it was considered by them that the money would be far better spent in a museum of mechanical inventions

and contrivances, and the different kinds of woods and metals used in workshops. The remarks made at the meeting he referred to showed that workmen were quite ready to make use of exhibitions of machinery and industrial appliances, and learn from them as much as possible. He therefore thought that museums of raw materials used in chemical processes, and their products, with illustrations of machinery and apparatus used, would do much to further chemical technology. Then as regards prizes and scholarships, it might not be within the power, at present, of the Council to vote funds for special prizes, etc.; but something might be done, he thought, with good results, in offering prizes for special proficiency in chemical technology—something after the manner of the City and Guilds of London Institute. This Institute offers prizes of from £1 to £5, with medals, etc., for proficiency in certain subjects. On the same principle it might be possible to establish scholarships. He considered that examinations in technology were too much upon paper; and they ought to have some better test of the knowledge of scientific facts and certain general details. He thought the best examinations would be in seeing candidates while at work, either in firing a furnace or working black-ash, or testing the work in making some textile fabric, and other really practical operations. Let the examinations be an actual test of the work done, and not the putting of certain printed questions to be answered on paper. He was still prepared to move that a committee be appointed to take cognisance of these matters.

The CHAIRMAN expressed a hope that some such a resolution as Mr. Tate had suggested would be passed. That Society might undoubtedly give support to any legislation that might be proposed for the improvement of technical education, and he thought Mr. Carey was quite right in considering the recommendations which the Commissioners had made. It was clear that the instruction given to workmen must be very different to that given to foremen and managers of works; but he thought it was very desirable that every workman engaged in chemical manufacture should understand something of chemistry, and some idea of the substances they were treating, and the behaviour of those substances, and the general laws which governed each. A stoker was all the better for knowing something of the laws of combustion. He did not see why elementary chemistry should not be taught in board schools, but he quite agreed with Mr. Brunner that science should not be taught by the ordinary school teachers. If they taught science at all, it ought to be taught in a proper manner. He thought the system adopted in Liverpool was a proper system, and he did not see why they should not have some such system at Widnes. The Royal Commission recommended that in rural schools instruction should be given in the principles of agriculture in the upper standards. He thought a similar thing should be done in a place like Widnes, and lessons given in the principles of chemistry, and so with other districts. But then they must go to something beyond mere elementary instruction. He thought it desirable to have the full course of instruction such as was given at The Owens College, where, so far as he had gathered, there was a most admirable curriculum. He agreed with Mr. Brunner that it would be far better for boys to enter such a college at the age of 16 and leave at 20, than to go at 14 and leave at 18. This curriculum had been in existence only four years, and he had not the slightest doubt after some years they would be able to improve upon the curriculum, but as far as it had gone it seemed to be a very efficient one. He was glad to hear Mr. Watson Smith quote from Sir Henry Roscoe, that after being taught

analysis and chemical preparations, pupils should devote themselves to some kind of original research. This was most valuable. It would draw forth their powers of observation, and it would be the most useful part of their education to fit them to take part in chemical works. He was glad that Sir Henry Roscoe had come to the same conclusion as he had himself, and made the same recommendation. Nothing as yet had been done by the Government upon the Report of the Royal Commission, but he thought it would be very desirable and of great advantage if a society like that, as well as the Iron and Steel Institute and other societies, should press upon the Government the absolute necessity of taking steps to follow the Commissioners' recommendations.

#### REPLY.

MR. WATSON SMITH: I entirely agree with Mr. Brunner's sentiments with regard to the advantage of the educational system of the board schools in different cities and towns, differing and varying as to degree or bias, both as regards kind and amount taught of the elements of Applied Science according to the nature of the staple industries of the cities and towns in question.

It is certainly desirable that mere boys should not enter the higher colleges too young, and in an unprepared state; their parents and guardians are sometimes too eager to send them early to college in order to take them away again too soon. I quite agree with the statement that they ought to go later, if that means *better prepared*, and stay longer, if that means *completing the educational course*, but I would like to add a word here: there are not a few who come not too young, but they come unprepared; *un schooled*, in fact. If such as these stay until old age advances they would scarce be able to recover what has never been gained at school. What I see great cause to complain of, is that amongst certain of our middle classes the question of the really sound, solid education of boyhood and youth in the schools, according to some rational plan, is not treated with sufficient earnestness. If something of the vigour, zeal and determination of purpose manifested in the various popular school games and sports, were insisted on in the mastery of even the lower elements of mathematics for those who are to study science afterwards in our colleges, then we should see fewer examples of young men utterly unable to rise in science, because almost incompetent to reason numerically, not to speak of mathematically. It is usually a grand blunder to assume or suppose—as I fear is often assumed or supposed—that an unschooled boy can make up his deficiencies at college; *as a rule, he cannot*; there are exceptions, *but they are few*. This blunder is one that is being continually made in this country; and it is the source of much perplexity to the teaching bodies of our higher colleges, much despair and disappointment when it is well-nigh too late to mend, to the student and his friends, *and of most of the failure of the young chemists of this country to compete with those of Germany*. Nearly all the energies and time of the teachers are consumed in teaching untaught birds to fly, as it were; so that strength, time and opportunity are shortened for the very few capable of soaring aloft. This too usual and general state of things explains, moreover, a point very properly called attention to by Mr. Carey, *viz.*, that it should not be possible for board school boys, in a general way, to enter at all easily, and compete, in the courses of the higher colleges. In these colleges we have not, as in Germany, in the main to deal with our subjects, starting from a certain higher platform; but we have to cope with the drawbacks and disadvantages already

prefigured, as far as we are able, by exercises, tutorialising, and the like. As an example may be mentioned what has already been openly styled, "chemical arithmetic," the great need of which is manifested in the numerous excellent little books published on the subject, which points—not so much to the difficulty of elucidating the chemical theories or the chemistry of certain experimental operations—as it does to an evident flaw in the previous systems of elementary mathematical instruction in the schools. Why, else, is it that such little books are never to be seen in Germany and Switzerland in connection with the universities and polytechnic schools? Our board school boys are taught to perform most of such calculations (at least in Manchester) with considerable ease, both in the branches of mechanics and chemistry. However, I believe I referred to the *chosen spirits of the board schools*; and since our lower class population is so vast, these "chosen spirits" may, peradventure, represent a respectable number. At The Owens College we have one small scholarship available in chemistry—*viz.*, the "Crace-Calvert Scholarship," and only that one, and this available but once in two years. This is at the present moment held by a former board school scholar; and I am bound to say he is by far the best man of his year. With regard to Mr. Tate's motion in its *present* form, it seems to me both a practical and a good one; and I believe the reports furnished by such a committee would be valuable in a variety of ways. The technical practice Mr. Tate describes—in work likely to be of future value to ship-builders and similar workpeople—would be very well for Liverpool lads, just the thing for Liverpool, but the bias in Manchester must be in another direction—*viz.*, that of chemistry, for in Manchester we have cotton bleaching, cotton dyeing, calico printing, and general chemical manufacturing, as our staple industries. However, I think I now see what one of Mr. Tate's objections to the City and Guilds of London Institute programme refers to,—*viz.*, the lack of laboratory trials and examinations in connection with the questions set. It must be remembered though, that these examinations of the City and Guilds of London are thrown open free of cost to the country; and laboratory or work-shop testing would entail vast expenses. Besides, if the theoretical side of the question is so crisped as to enable the candidates to pass these examinations, we need not complain; there is a lifetime to follow for utilising the theory in practice. With regard to the matter of what is termed "grouping," this is done as I have already described in my paper; but it is done in subservience, as I hold it should be, with the student at college, to the main thing,—*viz.*, the grounding and foundation in scientific principles. I believe the subject of strength of materials, and so on, is touched upon in the Geometrical Drawing lectures in our College; and as regards the further one of the chemical technology of building materials, mortars and cements, etc., this would be all very good for the practical engineer. However, our course of Chemical Technology in The Owens College is growing yet, and we have youth on our side, for our course was but founded in 1881. As to testing by examinations in technology taken in the narrower sense, such, *as*, examining a man on soda making, and then setting him to make a black-ash ball, and watching him do it, there I differ with Mr. Tate. Where the examination elicits evidence of general grasp and knowledge of scientific principles, there I follow; but where the mere manipulative skill, or the more specialised details, besides conscientious working and moral principle, are concerned, there I am sure we cannot intrude. As regards alkali making, moreover, in which there are no special secrets, even such manipu-

lative competitions might be conceived possible; but take another branch, that of dyeing, or of the manufacture of dyes and colours, and there, I imagine, there would be a difficulty, for no dye house or dye and colour factory, that I know of, would permit such a thing; and for a workman to enter into such competition would be regarded probably with sufficient suspicion by his employers as to secure for him the wide world to hunt in for a new post in which to exert his prowess. In answer to remarks by Mr. Alex. Watt, I do certainly consider that there is scientific principle involved in the making or manufacturing with certain regard to economies, and as both logic and political economy are scientific branches, so the economics of the manufacturing industries admit of scientific treatment. Such treatment is absolutely necessary, and I do not overlook its principles, by any means, in my teaching. Without bestowing some attention to these, how could one else elucidate the mysteries of the occasional practical reversal of the terms "chief products" and "by-products." In science, the key-note is, so to say, "truth for its own sake"; in technology, it modulates into "truth for the largest amount of tangible profit it can be made to yield." I fear that if the group of possible technical subjects were swelled by too many reinforcements, then chemical technology, as a study, would rise from being the handmaid of science for the student, to the position of the tyrant; and the grasp of scientific truths, and the march in the right path of acquirement of fundamental truth and laws, would be weakened and hindered by excess of technicalities, which could all be gained and learned in the life and practice of the future, when, however, the time for studying and learning scientific principles has fled. I think I read in the extract from the Report of the Royal Commissioners that the teaching of science in the board schools is not mainly delegated to the board school teachers; it is not so in Liverpool, Manchester or Birmingham; but these teachers hear the teaching of the chief instructor, and then help the pupils, in what they, as older and more experienced persons, have learnt and understood to better purpose than the children, their pupils have.

I am not sure if stress has been laid by the Royal Commissioners on the technological bias, if I may use the term, to be observed in different industrial districts; but from their report it is clear that this has followed as a natural consequence in Liverpool, Manchester and Birmingham. No doubt such data as these could be usefully collected and applied by a committee appointed by our Council, such as that proposed and under consideration.

It was then moved by Mr. TATE: "That this Section recommend the Council to appoint a Committee for the purpose of considering the subject of Technical Instruction, and taking such steps as may be deemed advisable to promote more of such instruction in this country, especially as applied to Chemical Industry."

Mr. CAREY seconded, and the motion was carried unanimously.

## Manchester Section.

### Local Secretary:

J. Carter-Bell, Bankfield, The Cliff, Higher Broughton, Manchester.

Notices of papers and communications for the meetings to be sent to the Local Secretary.

Meeting held Tuesday, January 20, 1885.

DR. HEWITT IN THE CHAIR.

THE CHAIRMAN: Words fail to express the feelings of all who have been placed in a similar position to that which Sir Henry and Lady Roscoe have so recently been called upon to endure, in the very sudden decease of one in whom their hopes were centred; and as I am sure there are many present who have realised those feelings, it will not require any lengthy explanation on my part in asking you to pass a vote of sincere condolence and sympathy with Sir Henry and his family, in the loss which they have sustained in the death of their son. I had not the pleasure of knowing Sir Henry's son, but I am informed that he promised to attain distinction in a somewhat different sphere from that in which his eminent father has become so well known, and that he has been cut off in the springtime of life and promise, adds bitterness to this deep bereavement. I will, without further comment, move the following resolution:—"This meeting desires to express sincere condolence and sympathy with Sir Henry and Lady Roscoe and their family in the sad bereavement they have sustained in the loss of an only son and brother."

Mr Wm. THOMSON, in seconding the vote of condolence, said: After attending the meeting of the British Association a few months ago in Canada, I saw Sir Henry's son at the Falls of Niagara, when he seemed to be in the enjoyment of robust health, and of the wonderful Falls, in the vicinity of which he remained during several days. I understand it was not his intention to follow in the footsteps of his father as a man of science, but in another direction he had already shown marked ability in a series of very cleverly written articles which appeared during last autumn in one of our Manchester newspapers, entitled, "Jottings from America," and which many of us must have read with pleasure. The loss which Sir Henry and Lady Roscoe have sustained by the untimely death of their only son, when he was about to enter on a career of the highest promise, is one with which we must all deeply sympathise.

The CHAIRMAN called attention to the "Rivers Pollution Bill" which had been introduced into Parliament, and which has come before the London Section, and said: It is hoped that the members of the Manchester Section will prepare themselves by obtaining all the information they can that will throw any light upon the matter, so that it may be fully discussed. It is a matter which will affect every manufacturer, and although of a practical nature, it is a subject upon which scientific knowledge must be brought to bear. I think it is the intention of the Committee to put it upon the notice paper for the next meeting, and any facts that can be adduced will be of the utmost importance. There is no doubt that this Society, consisting as it does of practical men, will have to make in its joint capacity some important reports to the Government on the matter. I need not say that any one who wants information upon the subject can find it in the voluminous reports which have been made in Parliament in former years. Some of the proposed tests of purity which were brought before the Rivers Pollution Commission on former occasions, and which proved to be impracticable, are again being introduced just as if no inquiry had been made. I hope that all who can will make some contribution to the subject, not merely for the sake of opposition, but for the purpose of showing whether it

is possible, without interfering with trade or manufacture, to render our rivers more sightly and purer than they are at present.

Dr. Bott's Paper on "Hempel's Methods of Gas Analysis," and Prof. Wanklyn's Communication will appear in the March number.

## Newcastle Section.

Chairman: J. C. Stevenson, M.P.

Vice-Chairman: B. S. Proctor.

Auditor: N. H. Martin.

### Committee:

J. P. Stark.  
T. W. Stuart.

Local Secretary and Treasurer: J. T. Dunn, 115, Scotswood Road, Newcastle.

Notices of papers and communications for the meetings to be sent to the Local Secretary.

Next meeting, March 5.—1. On the Proposed Statue to Nicholas Leblanc; 2. On the Recovery of Sulphur from Alkali Waste; 3. On a Furnace for Chemical Operations which is neither an Open Furnace nor a Close Furnace; and 4. On the Manufacture of Chlorine from Oxysulphide of Magnesium. By Walter Weldon, F.R.S.

Meeting held, February 12, 1885, in the Lecture Theatre of the Durham College of Science.

MR. B. S. PROCTOR IN THE CHAIR

## DISCUSSION ON THE NOTES READ AT LAST MEETING.

MR. MORRISON wished Dr. Lunge had stated the size of the pieces of metal operated on in studying the action of chlorates on them, and how their surface was determined. In multiplying the results to the actual size of the evaporating pans, any error would of course be greatly increased.

MR. TATTERS expressed his agreement with what Mr. Morrison had said.

MR. STUART thought that Dr. Lunge's well-known accuracy and skill might be relied on to avoid error wherever it was possible. It was, however, very difficult to imitate exactly the conditions of manufacturing operations in laboratory experiments. As a matter of fact, it was known that the pans suffered very little in practice.

DR. SMITH mentioned that in some very similar experiments which he had conducted in Dr. Lunge's laboratory, pieces of metal were used exposing a surface of about 20 square cm., and were accurately measured by a skilled mechanic.

## DISCUSSION ON THE "RIVERS POLLUTION BILL."

THE CHAIRMAN, in introducing the matter, regretted the unavoidable absence of the Chairman of the section, who would have spoken with authority on the matter. He called attention to Clause 26, and to the penalty in Clause 3, which he said applied to every household drain; and also to the loose wording of Clause 9, which made it appear that to escape prosecution under the Act, liquids must contain more than the quantities of the various contaminations mentioned. These were evidences of want of care in drawing up the Bill, and in dealing with a subject of so great importance, the greatest care was necessary. He then called on

MR. JOHN PATTINSON, who said: The "Rivers

Pollution Bill," which will probably be introduced into Parliament during the next session, and which we are called upon to discuss this evening, is a measure intended to supersede the Rivers Pollution Act of 1876, which has been comparatively a dead letter since its enactment. The present Bill is intended to remedy some of the defects of the 1876 Act as to methods of procedure, and also as to the definition of what in certain cases constitutes an offence under the Act. These defects have been described by Mr. C. N. Cresswell, in opening the discussion on this subject at the meeting of the London Section of this Society on the 5th of January last. Divested as far as possible of its legal verbiage, the scope and aim of the proposed Act appear to be as follows: In Clause 2 are defined what are to be considered as offences against the Act. In the first place it is an offence to put into a stream any solid matter so as to interfere with the due flow of the stream or alter its bed or pollute its waters, or to put in any solid matter which is putrid, poisonous, offensive or injurious to animal life. Secondly, it is an offence to put liquid or solid sewage matter into any stream; and thirdly, it is an offence to put into any stream any liquid containing matter poisonous, noxious, polluting, or injurious to animal life. In Clause 9 the Bill defines the term "stream" to mean that it "includes all rivers, whether tidal or otherwise, brooks, navigable canals, lakes and watercourses, except such parts of a tidal river as the Local Government Board may by order, published in the *London Gazette*, after local inquiry, determine on sanitary grounds not to be part of a river. It shall also include so much of the sea as the Local Government Board may by like order, and on the like ground, declare to be part of a stream." Having defined the offences under the Bill, it provides in Clause 5 that on the complaint of any conservancy authority or fishing board of the district, or of any occupier of land or a dwelling-house within the district, the sanitary authority of the district shall institute proceedings to restrain the commission of offences against the Act. If the sanitary authority refuses to institute such proceedings, or does not prosecute them with due diligence, the complainants may apply to the county court of the district for leave to institute proceedings themselves, and to prosecute them at the cost of the sanitary authority. Proceedings may also be instituted by any person who may consider himself aggrieved by the commission of offences against the Act. In the latter case it is provided that the Court may order the person who institutes the proceedings to give security for the costs of such proceedings. Persons of the latter class are further encouraged to institute proceedings against alleged offenders by clause 3, which provides that the offender "shall pay to the person complaining, or to such other person as the court may direct, such sum not exceeding fifty pounds a day for every day during which he is in default as the court may order." In case of proceedings being instituted for any alleged offence against the Act, Clause 3 provides that the county court may by summary order require any person to abstain from the commission of such offence, and "may direct any skilled persons to report as to the best means to be adopted for preventing any pollution, and may make the adoption of such means by the person who has committed the offence part of its order; provided always that the court shall not sanction the adoption of any mode or means of action for prevention of pollution that does not reduce the polluting matter to a less extent than is defined by the standards of purity" given in Clause 9. It is not very clearly so stated in any part of the Bill, but I think the inference may be fairly drawn that no liquids of any kind are

to be allowed to be put into a stream which are less pure than the standards given in Clause 9. The standards of purity are those recommended by the late Royal Commission on the Pollution of Rivers. Some of these in my opinion are too lax and some are too rigid and exacting. Clause 4 gives the right to either party in an action to appeal against the decision of the county court, and Clause 6 gives the right to apply to the Local Government Board for an extension of the time allowed for adopting methods for the remedying of pollution. Such is a brief description of the principal features of this Bill. It will be seen that it is a very sweeping and stringent measure, and that, if passed in its present condition, it is likely to press very seriously not only upon many manufacturers, but even upon householders of every class. According to Clause 8, every person who sends sewage matter through his house-drain into a sewer, and from thence into a stream would be infringing the Act, and would be liable to a penalty of fifty pounds, and ten pounds a day for every day he thus uses his drain, if it has been made since 1876, and if the stream is not such part of a tidal river as "the Local Government Board may determine on sanitary grounds not to be part of a river." Surely this is far too stringent a clause to be placed at present on our statute book. The inducements held out by the 3rd and 5th Clauses are likely to cause litigations and needy persons to commence harassing legal proceedings against manufacturers and others, and this seems to me to be an objectionable feature of the Bill. The proposed Bill, if passed, would press most disastrously on many owners of mines, and on many manufacturers. To comply with its requirements, owners of mines and collieries would have to provide, in many cases at great cost, subsidence tanks and subsidence reservoirs. To enforce such a measure in the present condition of mining and manufacturing would in many cases be tantamount to closing the mines or manufactories altogether. I have had much experience in the methods of dealing with the waste waters of paper works, and am well acquainted with the degree of purity which can be attained in these waters by the application of the best practicable means. I have no hesitation in saying that if the standard of purity given in Clause 9 *a* of this Bill were insisted upon in the case of these out-flow waters, and if the penalties were enforced, no paper mill could continue to exist. In many other cases there are slight and sometimes considerable discharges of comparatively innocuous matter from manufactories, in which it would be very difficult, if not impossible, to comply with the requirements of this Bill. A boiler could not even be sludged out direct into a stream without incurring the severe penalties of this proposed Bill. On the other hand, some of the standards of purity are far too lax. Standards *h* and *i* are of this character. To allow liquids possessing an acidity equal to that which is produced by adding two parts by weight of real muriatic acid to one thousand parts by weight of distilled water, or possessing an alkalinity equal to that produced by adding one part by weight of dry caustic soda to one thousand parts of distilled water, is to allow the admission of liquids which would cause certain and immediate death to all animals which might come within their influence. I have prepared solutions of hydrochloric acid and caustic soda of the prescribed strengths, and the members of the Section will have an opportunity of noticing how very much stronger these are than any liquids should be which are allowed to be run into a stream under most circumstances. The great fault of the Bill, in my opinion, is its rigid and unyielding character. It makes no allowance for the varying

conditions of the towns, and the varying character of the manufactures, and the streams with which it has to deal. It appears to me that the courts which have to adjudicate on alleged cases of pollution should not be bound down by the rigid conditions and standards of purity of this Bill, but that they should have the power of dealing with each case on its merits, and of insisting upon the adoption of the best known practicable means of preventing pollution. It is incumbent on every one likely to be prejudicially affected by this proposed measure to endeavour to get it modified before it passes into law, and I think the various sections of the Society of Chemical Industry are acting wisely in calling attention to the matter. I beg to move the following resolution:—"That this meeting of the Newcastle Section of the Society of Chemical Industry, being of opinion that the proposed 'Rivers Pollution Bill' is inadequate to the objects of its promoters, and injurious to the interests of manufacturers, recommends its early consideration by the Council of the Society, with a view to such action on its part as the interests of Industrial Chemistry may require."

Mr. T. W. STUART: I have great pleasure in seconding the resolution. The Bill will press very hardly on manufacturers and mine-owners. The standards of purity are such as in many instances cannot be worked up to.

Mr. JOHN MORRISON: What has struck me most is Mr. Crookes' proposal, mentioned by Mr. Cresswell, that each river should form its own standard of purity; that seems to me to be the best form the measure could take.

The resolution was then put to the meeting, and carried unanimously.

University of Glasgow.

Notices of papers and communications for the Meetings to be sent to the Local Secretary.

A Meeting of this Section will be held in the Rooms, 207, Bath Street, on Tuesday, 3rd March, at 8 o'clock P.M., when Mr. James Murrie will read the following papers:—(1.) "On the Processes employed in Italy for the extraction of Oils, etc., from bituminous rocks in that country." (2.) "Description of a series of New or Improved Thermometers for taking High Temperatures."

A meeting of this Section was held in the Rooms, 265, Bath Street, on Tuesday, 3rd February, 1885.

MR. E. C. C. STANFORD IN THE CHAIR.

## ON BROMINE ABSORPTIONS.

BY EDMUND J. MILLS, D.Sc., F.R.S.; AND

JAMES MUTLER.

IN two previous communications to this Society (*Journal* 1883, 435; and 1884, 366), a series of constants of Bromine Absorption has been tabulated for a variety of oils and fats. In the present paper we give results for most of the important resins, for a few elements, and some interesting bodies of a different nature.

Throughout our work we have felt no personal ill effects arise from a few days' use of carbonic disulphide; accordingly we have employed it or carbon tetrachloride indifferently, as happened to be convenient; it being probable from certain experiments that, when small quantities of substance are taken, the absorption is almost always the same in either solvent. We have, however, indicated in all cases which solvent has been employed.

As regards resinous bodies, we found it best to proceed as follows:—The finely-powdered resin was placed overnight (together with the usual 50cc. of solvent) in the colorimetric bottles, and the next morning the bromine absorption was carried out. Sometimes  $\beta$ -naphthol was used for "titrating back," more particularly—as in the case of pale resins—when the bromine derivatives had but little tint. Sometimes the operation was finished with hyposulphite (thiosulphate) and decinormal iodine, and sometimes the purely colorimetric comparison alone was employed. Except where otherwise stated, all the results are means of at least three determinations.

The letters S. and L. indicate that disulphide or tetrachloride was used respectively. The letters N., H. and C. indicate that the absorption was finally, measured by  $\beta$ -naphthol, hyposulphite or simple colorimetry. In nearly all cases the time of contact with bromine did not exceed an hour.

The names marked (\*) represent commercial varieties of dragon's blood.

It will be observed that our experiments are divided into three groups, relating to (1 to 14) varnish resins, (15 to 34) tinctorial resins, (35 to 38) elements, (39, 40) oils.

The following substances gave no absorption in tetrachloride:—Benzoic, cinnamic, and salicylic acids; camphor, naphthalene and benzaldehyde.

The results with anthracene in tetrachloride were very peculiar. At 11° C., and with very cautious addition of standard bromine, the absorption was 88.67 per cent.; corresponding well with the ratio,  $C_{14}H_{10} : Br_2$  (89.89 per cent.). At about 17°, the reaction was violent; much hydrobromic acid came off, and the absorption was 175.33 per cent., corresponding approximately with the ratio  $C_{14}H_{10}Br_4$  (179.78 per cent.).

Some interesting features are noticeable in the tabulated results. Thus, the extraordinarily low absorption of shellac gives it a unique position among resinous bodies; and gum amber is distinctly below all other substances of its class. "Boiling" makes a measurable difference in copal; from which, again, kauri differs greatly. As a rule,

but not invariably, the more soluble a gum resin, the greater is its bromine absorption.

For samples of all the tinctorial resins, excepting gamboge, we were indebted to Messrs. Dobbie and Henderson, who were at that time themselves investigating them from another point of view. Our bromine absorptions amply support their conclusion (*Pharm. Journ.*, Nov. 10, 1883), that the term "dragon's blood," represents several fundamentally distinct resins. The same may be certainly said of the xanthorrhoea resins.

As regards elementary bodies, it is remarkable that tin dust will not take up bromine in presence of carbon tetrachloride. The absorptions for commercial arsenic and aluminium are very peculiar, and would well repay further examination. Zinc dust takes up bromine in the proportion  $Zn : Br_2$  (calculating 24.65 per cent. for pure zinc); and antimony in the proportion  $Sb : Br_3$  (calculating 200.00 per cent. for pure antimony, our commercial sample apparently containing about six per cent. of impurities).

*Aniline and Toluidine.*—The great technical importance of these amines has induced us to devote special attention to them. It has already been shown (*loc. cit.*, 1883), that aniline, dissolved in carbon disulphide, absorbs bromine in the ratio  $C_6H_5N : Br_2$ . It is probable, in this case, as in that of the toluidines, that "additive" and not "substitution" compounds are formed. Our experiments with the toluidines relate to ortho- and para-toluidine only. Aniline oils contain very little meta-toluidine.

*Para-toluidine.*—This is the solid modification. The specimen had been prepared by one of us for a research on melting-point, and could be completely depended upon. Taking disulphide for the solvent, a standard solution of bromine, containing 0.115 grm. in 1cc., and a weak standard solution of toluidine (in order to save repeated weighings), we found the results very irregular, and on the whole much too low, when quantities exceeding 0.4 grm. were employed. With that amount and under, the mean of three experiments gave an absorption of 7.447 per cent., with a probable error of .18. This is in accordance with the ratio  $2C_7H_7N : Br_2$ , which requires 7.477 per cent. We also made a series of experiments with tetrachloride as the solvent, varying the strength of the standard bromine from 0.093 grm. to 0.032 grm. per cc., and the weight of toluidine from 0.1 grm. to 0.3 grm. The mean of five absorptions was 81.03, with a probable error of .42. The chemical activity of para-toluidine in carbon disulphide is clearly less than in the tetrachloride; in the latter solvent, larger quantities than 0.3 grm. always seem to yield yellow by-products. It is evident that in this case the disulphide is a more advantageous solvent for analytical purposes.

*Ortho-toluidine.*—For this liquid modification we took 0.25 grm. toluidine, disulphide as the solvent, and standard bromine containing 0.0483 grm. in 1cc. The mean of six experiments gave an absorption of 151.34 per cent., with a probable error of .53. The ratio,  $C_7H_7N : Br_2$ , requires 149.53 per cent. Our specimen, obtained from Kahlbaum, may possibly have contained a little aniline; but the difference from theory is only about 1.2 per cent. on the percentage. The chemical difference between ortho- and para-toluidine is very striking.

*Mixtures of Aniline with Para-toluidine.*—If the bromine absorption of a mixture of aniline with toluidine be known, the composition of the mixture admits of ready calculation. The quantities of mixture which we took were .02 or .025 grm., the solvent being disulphide. Each result is a single

mination. But we must remember that the difficulties disappear when care and time are taken; those who have tried the process have soon got over them, and there is no lack of analysts who now practise the method. The analysts representing the London water companies determined in 1883 the organic carbon and nitrogen in daily samples of all the London waters, and they still continue to employ it. The independent monthly reports to the Registrar General also state organic carbon and nitrogen. This combustion method has also been employed with satisfactory results for the analysis of small quantities of organic substances obtained in original research. On the whole, then, we may take it for granted that a comparison of any given effluent with the proposed standards can always be had, if desired.

The standard suggested for organic nitrogen is  $\frac{1}{3}$ , exactly ten times the amount of the standard proposed for potable waters in 1874. Thus the Act can hardly be said to be of too severe a character as regards organic pollution. It might perhaps have been desired by some that "albuminoid ammonia" and "acid permanganate" standards should have been proposed. Both these processes undoubtedly detect very bad waters, and might conceivably serve the purpose of an Act. In my opinion, however, the proposers have done well to say nothing about them. These methods determine a fraction only of the carbon or nitrogen, as the case may be; it is certain that, in many cases, the value of this fraction can be increased by simply prolonging the action of the re-agents, and it appears to vary with the season of the year. Results of this nature are clearly less definite than those of combustion. The combustion process goes to the root of the matter at once; it gives us an entire and perfectly distinct result, with all desirable precision.

(b) *Acidity*.—The proposed standard is two parts per 1000 of real muriatic acid; it was originally laid down in the interests of fish life. As regards the susceptibility of fishes to chemical re-agents, the best work with which I am acquainted is the report (1868) of Penney and Adams, published in the Fourth Report of the Rivers Pollution Commission. These experimenters show that one part of muriatic acid in 10,000 is fatal to fish, while of sulphuric or nitric, as little as one part in 50,000 will suffice. The standard is therefore at least 100 times too great.

(i) *Alkalinity*.—The proposed standard is one per 1000 of caustic soda, but according to Penney and Adams, one of caustic potash in 35,000 is a fatal proportion. The limit for lime has not been determined, but is known to be very low. Again, alkalinity is one of the most effective conditions for the development of bacterial life, and could not fail to intensify the foul state of the foreshores in many places. In my opinion it is not necessary or expedient to permit any alkalinity, however slight.

(f) *Chlorine*.—The effluent, after acidification with sulphuric acid, is not to contain more than one part per 100,000 of free chlorine. By re-calculating the results of Penney and Adams, I find that  $\frac{1}{5}$  per 100,000 is a fatal proportion. Here again the standard is not sufficiently restricted.

Viewing the Act generally, I cannot but think that a clause is required disclaiming all *permission* of pollution up to the limits of the standards. No one, for example, ought to be allowed by law to foul a stream, already pure, by converting it into a  $\frac{1}{2}$  per cent. solution of hydrochloric acid. Riparian proprietors ought, in such cases, to have their existing rights reserved to them. Let us also trust that all manufacturers may be treated alike.

As regards the outlook for manufacturers, there can be little doubt that in many cases it will be necessary to erect subsidence and treatment tanks and filters,

and in all cases to collect and store the rainfall. This will be required for dilution and flushing. Land, therefore, will be in demand in the neighbourhood of country and suburban chemical works. Urban factories unable to purchase ground will have to execute works to perform the purification vertically instead of horizontally, but in many cases this plan will necessarily fail, discharge into the sewers must still be had recourse to, and the question will become one of sewage purification. On the whole, I should strongly advise manufacturers to support the early passage of this or a similar Act. As the popular knowledge of this subject is constantly improving, we may depend upon it that postponement will not bring easier terms.

Summing up, then, these considerations, it appears to me (1) that an Act for the better prevention of the pollution of rivers is urgently required; (2) that the principle of standards is a good one, and ought to be maintained; (3) that the proposed standards are of a very liberal character, and perfectly accessible to analysis; but (4) that the chlorine, acid, and alkali standards are not sufficiently stringent to preserve the life of fish.

Dr. WALLACE: I have examined the new "Rivers Pollution Bill," with some care, and am glad to have this opportunity of expressing an opinion as to its merits and demerits. While, upon the whole, it is a distinct improvement on the Bill of 1876, it is imperfect, and I believe unworkable in many particulars. It appears to have been drawn up by men who, however eminent in scientific attainments, are only partially acquainted with the requirements and necessities of manufacturers. I have no doubt, however, that before the Bill is passed it will receive important modifications, such as would suggest themselves to any chemist who has had extensive experience in the difficulties of dealing with manufacturing pollutions.

At the outset I may refer to a very important part of the Bill of 1876—that is, section 7—which requires "sanitary authorities to afford facilities for factories draining into sewers," to quote from the rubric. It is proposed to repeal the Act of 1876. There is nothing in the new Act corresponding to the section to which I have referred, and I consider it a very important omission. I know of a case which dragged its weary course along for many months, the decision on which turned entirely upon this section 7 of the 1876 Act; and I have no doubt that there are many similar cases. It is necessary, therefore, that there should be some explanation regarding the omission of similar provisions in the Bill now under consideration.

The Act of 1876, except in so far as the section referred to is concerned, is about the most colourless and useless piece of legislation that can well be conceived; for all the prohibitory and preventive clauses are so explained away and hedged about with conditions that they are practically inoperative. We cannot say this of the proposed Bill of 1885, for the provisions are in some respects very stringent, and there is no escape from them. In one particular, however, the framers of the Bill are indulgent to a fault. They propose to admit into a river, stream or sewer any liquid possessing an acidity not exceeding two parts per thousand of real hydrochloric acid, or 140 grains per gallon. The admission into a river, still more into a sewer, of such a large quantity of acid is, in my opinion, most objectionable, and likely to lead to constant complaints. I would entirely prohibit the admission of acid of any kind to sewers or rivers; and I would have the less hesitation in doing so, because acid is easily neutralised by passing the refuse water over a bed of chalk or limestone, as is done in our own neighbourhood by Messrs. Stevenson & Carlile.

I propose now to refer to the standards of purity in the order in which they are printed in the Act. (a.) stipulates that no liquid containing in suspension more than one part of dry organic matter, or three parts of dry mineral matter per 100,000, shall be permitted to enter a stream. These quantities, being respectively 7 and 21 grains per gallon, are, in my opinion, too small, and should be, at least, doubled. The river Clyde, above Glasgow, contains, during heavy floods, as much as 11 grains per gallon of suspended matter, mostly finely divided clay or mud; although in ordinary times the quantity is very small. Below Glasgow, ranging from Govan to Dumbarton, it contains, during ordinary weather, from 1 to 2½ grains per gallon of suspended matter, of which from ¼ to ½ is organic. No doubt the Clyde is a polluted river; but on many occasions the pollution in it and rivers generally, is caused, not by sewage or manufacturing refuse, but by the detritus of cultivated land; and is, therefore, entirely beyond the control alike of local authorities and manufacturers. On one occasion I had an opportunity of taking samples of the effluent from the sewage works at Birmingham, and of the river flowing into which the purified sewage flows. The effluent contained 9 grain per gallon of suspended matter, while the river water had 14.2 grains, so that the sewage actually helped to purify the river. The same thing occurs at Bradford, when the sewage effluent, after filtration through breeze, is practically clear and colourless; while the water of the Beck is as black as ink, and very muddy besides. I admit that the rivers to which I have referred are more or less polluted, and would be vastly improved by the rigid enforcement of such an Act as that under discussion; but I fear that the high standard of purity aimed at is practically unattainable, or can only be attained by a pressure on our manufacturers, which will be very hard to bear, and which will inevitably lead to all sorts of evasions of a similar character to those practised under the Alkali Works Act. There is no one more anxious than I am to see our rivers restored to their pristine purity; but there is a possibility of pressing the manufacturers too hard, and driving the production into other countries, where such restrictions are unknown. If the proposed standards, as regards matter in suspension, were doubled, there would be no practical difficulty in complying with them. It is in this, as in many other things, the last straw which breaks the camel's back.

We now come to (b.), relating to organic matter in solution. This it is proposed to limit to two parts per 100,000 of organic carbon, and 3 of organic nitrogen. This I find, on calculation, to be sufficient for all properly purified sewage; but in regard to manufacturing refuse water it is a standard compliance with which would entail very great hardships upon proprietors of works of various kinds. Here, for instance, is an example of waste water from a paper mill draining into a beautiful river in the north-east of Scotland; the caustic liquor, of a dark brown colour, but not strong enough to pay the cost of evaporation, contains upwards of 2000 grains of organic matter per gallon, the spent bleach 55 grains, and the general drainage of the works, mostly washings, 50 grains. In the case of another paper mill in our own vicinity, the general discharge of the whole work contains 334 grains of organic matter per gallon. Now, the standard in this Bill, two of organic carbon per 100,000, is equal to only 3.5 grains of organic matter per gallon; and these works could not possibly comply with it. No amount of neutralising, settling, or filtration would reduce the organic matter so as even to approach the standard; and it seems to me that if the Bill were to pass into law in its present condition, it would simply put a complete stop to the operations of every paper mill

in the country. There might, indeed, be a door of escape for those who were so situated that they could turn into their works an enormous volume of clean water, so that their discharge would be diluted ten or twenty fold; but this would be a mere evasion of the Act, and one which comparatively few manufacturers could take advantage of. Again, with regard to dyers, I had recently an opportunity of examining the final effluent of six dye-works, and in all cases the amount of organic matter in solution considerably, and in some cases greatly, exceeded the proposed standard. Distillers making raw grain whisky give a discharge which contains an enormous amount of dissolved organic matter; in one particular case, recently investigated, it contained 840 grains of dissolved organic matter per gallon, and in another no less than 2466 grains. I admit that a considerable proportion of this consisted of albuminous compounds, dissolved in lactic acid, which, if neutralised by lime, as is done to a partial extent in some distilleries, would have been precipitated; but even after this the discharge would have required an admixture of at least a hundred times its bulk of pure water to bring it down to the standard. I shall only refer to two or three instances recently brought under my observation: A tar distilling work gave a discharge containing fully 400 grains per gallon of dissolved organic matter, a tannery 72 grains, an oil-refining work 49 grains, a gut work fully 600 grains, a skin-dressing work 186 grains, a soap work upwards of 2000 grains, a slaughter house 26 grains. In fact, there is scarcely a manufacturing operation in which animal or vegetable substances are treated, in which the waste water does not contain an amount of dissolved organic matter largely in excess of the proposed standard; and I trust the manufacturing interests of the country will not be hampered by such conditions as would, in a great many cases, simply mean annihilation.

The next standard (c.) refers to colour, and it is a very absurd one. It condemns "any liquid which shall exhibit by daylight a distinct colour, when a stratum of it, one inch deep, is placed in a white porcelain or earthenware vessel." This is far too indefinite: what is a distinct colour to one person would not be held to be so to another.

(d.) "Any liquid which contains, in solution, in 100,000 parts by weight, more than two parts by weight of any metal except calcium, magnesium, potassium and sodium." This I think is sufficiently liberal for all ordinary manufacturing operations, but in regard to water pumped from mines containing shales highly impregnated with pyrites, and the drainage of blaes heaps of a similar character, there would be some difficulty. These waters frequently contain, besides much free sulphuric acid, 100gr. per gallon, or more, of oxide of iron and alumina in the form of sulphate, and the treatment of the water is both troublesome and expensive. At the same time it is most desirable that these refuse waters should be treated, and the oxide of iron and alumina separated, before they are permitted to enter a stream. I know one considerable river the water of which has been completely destroyed by mine and blaes-heap waters. On mixing with a large body of river water containing a certain quantity of lime and magnesia as carbonates, the acid is neutralised and a early precipitate of oxide of iron with a little alumina is formed. This gets into the gills of fishes and is very destructive of life. The river I refer to was formerly celebrated for its trout, but I understand that fish has now entirely disappeared.

(e.) Refers to arsenic and (f.) to chlorine (set free by the addition of acid), and I don't see any reasonable objection to them.

(g.) "Any liquid which contains in 100,000 parts

by weight, more than one part by weight of sulphur, in the condition either of sulphuretted hydrogen or of a soluble sulphuret." The difficulty I see in this provision is in regard to the drainage of heaps of alkali-waste, such as exist at St. Rollox and in the Newcastle district, Widnes, and several other towns in England. There are also in various places in the mining districts of England and Scotland enormous bins or heaps of blast-furnace slag, some of which, at least, contain enough sulphide of calcium to give a drainage water of a similar character to, although not so strong as, that from alkali-waste. The quantity it is proposed by the Bill to permit is 7 of a gr. per gallon, but what do we find in practice? Why in the drainage of the Pinkstone Bog at St. Rollox there is over 900gr. per gallon of sulphur existing as sulphide and liberated as hydric sulphide in the addition of an acid, and in the general drainage of the heaps of alkali-waste there is more than 200gr. per gallon. Now, it is all very well for a scientific chemist to sit quietly in his laboratory and lay down the law to manufacturers—you shall not do this or that; but what are the manufacturers to do? Take the case of St. Rollox. I suppose it is no exaggeration to say that there are there something like 20 acres of ground covered by alkali-waste, and this will give an average daily drainage of, in round numbers, 50,000 gallons, a quantity the chemical treatment of which would be attended with considerable expense. More serious still is the question what to do with the drainage of the Pinkstone Bog, which derives its sulphur compounds from the same source which, although very strong in sulphur viewed as refuse water, is by far too weak to enable it to be treated chemically with any hope of recovering more than a mere fraction of the cost of working. These are an example of practical difficulties which should not be ignored in making out an Act of Parliament.

I have already spoken of the section relating to acidity, but (*i.*) relating to causticity demands a passing notice. It is proposed to allow in water flowing into a stream or river an alkalinity not greater "than that produced by adding one part by weight of dry caustic soda to 1000 parts by weight of distilled water." This is 70gr. per gallon, but whether it is intended by *dry caustic soda* to mean  $\text{Na}_2\text{O}$  or  $\text{NaHO}$  I am not quite clear. In any case the allowance, as applied to the general drainage of a work, such as a paper mill, is sufficiently liberal, in fact rather too much so. Now the alkalinity may be caused by either potash, soda, or lime: and although I am not prepared to say that the effect of the two first mentioned alkalies would be very injurious to fish life, except perhaps in the immediate vicinity of the outfall, I am certain that lime in this proportion, which would be, in fact, lime water of nearly full strength, would be most destructive. The mere fact of the injurious action of lime is well known to the riparian proprietors on all rivers stocked with salmon and trout, but I am not sure that the cause of the destructiveness has been explained. My own explanation, which I offer with extreme diffidence, is that the lime, becoming carbonated, forms a precipitate which gets into the gills of the fish and impedes their natural action. A very moderate quantity of lime introduced into a small river has been known to kill thousands of fish. This clause, therefore, would require some amendment.

The last clause (*k.*) applies to petroleum or hydrocarbon oil, the quantity of which is limited to '05 per 100,000 parts, or '035 of a grain per gallon. This relates only to oil floating on the surface or in suspension, but a much greater evil in connection with discharges from paraffin oil works and tar and ammonia works is the tar-acids existing in solution.

It is true that these would be restricted by the clause relating to organic carbon in solution, but the amount allowed under that section would be infinitely more objectionable than the '035 per gallon in suspension. I know of cases where great difficulty has arisen from the presence of a small quantity of tar-acids in water.

I am of opinion that there should be a clause obliging manufacturers to mix all their drainage waters together and allow them time to react upon one another and settle thoroughly, for which purpose at least two tanks, each capable of containing a day's produce, would require to be provided. It is no uncommon thing to see two discharges from a factory, one acid and the other alkaline, and these passing into a stream at different places. A great amount of purification frequently results from the mixture of various effluent waters, and there is often a considerable precipitation. It is most important that the precipitation should take place in the works themselves and not in the bed of the river.

The greatest difficulty in carrying out the provisions of this or any other Act for the prevention of River Pollution will occur in the case of factories situated in large towns where ground required for the erection of tanks is very expensive, and in many cases unattainable at any cost. It may be said that those who have no such accommodation or cannot procure it should not be allowed to continue their business. It is also a truism that no man should have a family who cannot provide for its wants, but as a matter of fact such cases are only too numerous. The industries upon which the prosperity of the nation depends should, if possible, be led, not driven; and at all events not improved off the face of the earth by restrictions with which, in very many cases, it is impossible to comply.

In conclusion, I enter my protest against the principle of making a hard and fast rule applicable to all cases, no matter what the circumstances may be; and, especially demanding a higher degree of purity in an effluent or discharge than exists in the river into which it flows.

Mr. E. C. C. STANFORD said: Our Society is not an exclusive one. We are always ready to accept light and intelligence, whether they come from the outside or inside. I am very glad to see present to-night several gentlemen who are eminently qualified to speak on this subject. Although they do not belong to us at present, perhaps they will soon. I have much pleasure in seeing Professor James Thomson, Mr. Deas, and Councillor Smith. All these gentlemen will no doubt give us something worth carrying away.

Mr. DEAS (Engineer to the Clyde Trust) said: I am very glad to learn, for the first time, that there is a prospect of some legislation on the purification of rivers. I think there is no river suffers more, in the kingdom of Scotland at least, than the unfortunate Clyde. When I consider we have to dredge about 500,000 cubic yards of deposit every year, the bulk of which is from the detritus of the streets, manufacturing waste products, and from sewage deposit, I hail with pleasure any prospect of getting an alleviation of the heavy burden that the unfortunate Clyde has to bear. There can be no doubt that the River Clyde is a great deal more impure than it once was. You don't see any salmon further up the river now than Dumbarton Castle, and no fish will live from Bowling up to Glasgow. I should hail the day personally when an Act such as you have been discussing to-night would bring back the fish to our rivers and enable us to see the salmon sporting at the Broomielaw. I fear, however, this is a prospect that we have little chance of seeing.

Councillor SMITH said: I came here to-night to

learn, not to speak. I expected to hear something concerning this Rivers Pollution Bill, for certainly we do need a Bill of some kind or another. There are, however, vast difficulties that present themselves to my mind, both from a chemical point of view, as has been described to you to-night, and from an executive point of view, in putting any Bill into operation. We have a vast number of people who maintain that rivers are the natural arteries, for the carrying away of the *debris* of pollution. We have the opinion of one of the most eminent agricultural chemists, given at the last River Thames Commission who in his report maintained that the whole of the London sewage went to feed the fish in the North Sea. I refer to Sir J. B. Lawes, who wrote a letter, which the *Times* published *in extenso*. I candidly confess that I felt puzzled in reading this letter, and could not see how any sewage could help the fish in the North Sea, about 40 or 50 miles away. This, however, is Sir J. B. Lawes' view, and it is hard to say anything in opposition to such a scientific agricultural chemist, and you will easily see that there is great difficulty in carrying any Bill that will not present to any man vast variety of action. It is all very well to say that so many parts of acid and so many parts of liquid can be allowed to go into a river, but you will easily see that if half a dozen works have some pollution issuing from them the river will get into a highly polluted condition, and yet they are all acting in accordance with the Bill. I have felt this a great difficulty, and if you permit pollution of this kind to flow into a river it ultimately becomes entirely polluted. I confess to you that the more I look at this question of pollution I feel the greater difficulty in knowing what to do with manufacturers, for as Dr. Wallace has shown you there are a great many who have no ground to operate on their water, and what are we to do with these men? Either the community must supply sewers to take this matter down to a purification place, or must permit them to use the public sewers, and we all know what a nuisance these are to the inhabitants of the cities. The difficulties of this question are certainly great indeed, and all that can be done is to grope steadily at it, and we will ultimately come to some clearer idea of it than we have at present.

Mr. COLEMAN said: I am scarcely prepared to offer any observations, but I have a little experience in works which help me to say a few words. It appears quite clear to me that the standards of purity, which are proposed to be universally applied, would be utterly impracticable to carry out. There is nothing in my opinion to prevent standards being established for different parts of the country, by grouping the local authorities, appointed under the Bill, into districts.\* I think the Bill requires very considerable modification, and probably if it is so modified might become satisfactory. The scientific basis on which these standards are proposed is, I think, not perfectly clear. For instance Professor Mills' opinion is that alkaline water is to be avoided, because it encourages bacterial life, but we have the opinion of Dr. Angus Smith that putrefaction is the best possible thing to occur, because it gets rid of the organic matter. Moreover it may be a question whether the presence of organic matter may not be sometimes an actual benefit to fish as food; so that to lay down any general rule or establish any general principle by which standards can be framed for the United Kingdom is, I think, utterly futile.

Dr. CLARK: It appears to me that the proposed Act is a considerable advance upon the Act of 1876. There can be little doubt that the present Act is a

dead letter; and when we look to the cause we are led to the conclusion that this is due, in part, to the definitions. Thus, the Bill "prohibits solid matter from being discharged into streams," and when you come to the definitions you find that "solid matter" does not include matter in suspension, and that discoloration is not to be regarded as pollution. Again, we find also that, under the present Act, the sanitary authorities of the Local Government Board are the only parties who can institute proceedings against offenders; and they are expected to take into consideration whether there are good practical means of removing the pollution, and whether it would affect the trade or manufacture in question. Under these conditions, where there is so large a discretionary power, it is not surprising to find that the sanitary authorities are not inclined to take any proceedings against offenders, however great. In the present Bill, I observe that sanitary authorities will have less discretion allowed them, and that I consider a good feature. Another good feature is the introduction of standards. Without some standards of purity we are not able to grapple with pollution. We must, in my opinion, have standards laid down to enable us to decide what is pollution and what is not. The question, then, comes to be what particular standards are to be adopted? With most of the standards proposed I can find very little fault. I consider that rather too much acid and alkali is allowed; and I have no fault to find with the allowance of matter in suspension. The only two points to which I would take exception in the standards, are (1) "the limit of two parts by weight of organic carbon in solution." In some cases this is a considerable allowance; but in others, when the organic matter is of a harmless nature, it would press very hard upon manufacturers. Perhaps the particular standard of purity to which I take most exception is standard (c), which follows: "Any liquid which shall exhibit by daylight a distinct colour when a stratum of it one inch deep is placed in a white porcelain or earthenware vessel," etc. Now if this was very strictly interpreted, there are very few liquids which would pass this standard; and we know that many of our waters, especially those of a mossy or peaty character, have a distinct colour when seen in a stratum of one inch deep. In order, therefore, to make this a practical standard, it is necessary to compare the colour of the discharge with the colour of the particular water as it reaches the manufacturer. It is only in that way that you can ascertain whether a water is polluted; and I think it only fair to allow the manufacturer some little increase upon the amount of colour—to what extent I am not able to say—otherwise it would be practically impossible for him,—especially if he is the owner of a dye works, or some work where coloured materials are used—to discharge his water into the stream again. In other respects I think the Act is, as I have already stated, a step in the right direction.

Mr. TATLOCK said: I object to the Bill on two general grounds: first, because it treats all manufacturers alike. It is quite plain to every one who has a knowledge of a variety of manufactures, that while it would be quite easy, in some cases, to comply with the requirements of the Bill, it would be a matter of extreme difficulty, in fact it would be practically impossible, in many others to do so; and sufficient examples have been given. Second: I object to the Bill because it treats all rivers alike, no matter what their character or situation may be. It is evident that, while a commercial river like the Clyde, receiving so many discharges from chemical works, is not expected to attain to any great degree of purity, as the result of legislation, it is most desirable that rivers which are still unpolluted should remain so. I hold, therefore,

\* Chemical referees being appointed for each district.

that much more stringent legislation is required for those streams which have not as yet been defiled, than for those which have been for many years in a polluted condition. I also am of opinion that some of the standards of purity are too loose, and others too stringent.

Professor MILLS said: As regards the hardship to individual manufacturers. No doubt there are many cases that would necessarily arise, especially in the case of manufacturers who have standard processes which have been going on for a great many years, and resulting in a great deal of pollution; they cannot be expected to reform these in a short time. I certainly think, in a vast majority of cases, that the pollution might be very fairly dealt with by an Act of this description; and in the majority of cases there would be no hardship. If I were about to set up a dye works, such as exist in the Vale of Leven, I should prefer to do so in the heart of Glasgow. I am quite certain that any pollution I should produce would be more leniently dealt with in any future bill, than it would be if I had gone to the outskirts of Glasgow. I think that we neglect sea water in a great many towns not far from the sea, that greatly pollute rivers, where it would be easy to pump up water to wash down the impurities. Then, again, after all that has been said and done, there will be cases of extreme hardship, and cases with which the scientific chemist cannot immediately deal. I think if there was a court of appeal to certify the cases that are exceptional, and a committee of experts appointed by the Home Secretary to see what could be done, that it would meet this difficulty fairly well. It has been thought desirable by the Council of the Society that we should come to some resolution on the matter; and as there is, I think, a general consensus of opinion that such an Act is necessary, although not perfect as regards detail, I therefore propose for your acceptance the following resolution: "That, although this meeting considers the subject proper for legislation, it does not approve of 'The Proposed Rivers Pollution Bill,' in many of its clauses, and instructs the committee of the Section to make such communications, as it may see fit, to the General Council of the Society."

Dr. WALLACE, in seconding the resolution, said: This resolution does not bind us in any way. It is simply an expression of what we have virtually decided upon—that the Bill, although good in the main, is imperfect in many of its details. It only commits us so far as that; and we, as a meeting, throw the matter upon the committee to report to the General Council in London upon the subject. The General Council have asked our opinion on this subject, and the least we can do is to give them the benefit of our counsel and advice.

Mr. STANFORD, in putting the resolution to the meeting, said: I would simply add that I am quite sure the committee will do their best to put the prominent points that we object to in this Bill before the General Council. I would mention one particular with regard to the standards, that although some of them have been proved by Dr. Wallace to be high (I allude to the carbon and nitrogen), those for the acids and alkalis are far too low. No one would dream of running a waste liquor into the river having anything like the acidity or alkalinity allowed by the Bill. It is remarkable that while so much is said about quality, nothing is said as to quantity, thus, as Dr. Wallace has already said, evasions can very easily be carried out. He fancied, probably, that they would not be, but my impression is that they would. There is no doubt that nothing can be easier than to pump a large amount of water from the river to dilute the effluent

down to these standards and thoroughly come under the Act, and yet at the same time pass the same amount of pollution into the river. That appears to have been overlooked by the authorities. But why should we have any standards at all? It appears to me that a simpler way would be to require every one to put back into the river the water he drew from it in no worse state than he got it. With regard to the case of the Bradford Beck, to which allusion has already been made, it does seem absurd that the Corporation should have been interdicted for several years from passing their sewage into that river when it was thoroughly well proved that it would have made the river half as good again. My own opinion goes in favour of the suggestion made by one of the speakers in London, that we should go back to the Rivers Conservancy Boards. I think the rivers do want looking after, and would, in my opinion, be better looked after by a Board which does nothing else.

The motion on being put to the meeting was unanimously adopted.

## Obituary.

### SIDNEY GILCHRIST THOMAS.\*

BORN APRIL 1850; DIED FEBRUARY 1, 1885.

WE regret to announce the death, at Paris, on Sunday morning, February 1, of Mr. Sidney Gilchrist Thomas, to whose genius and untiring labours the basic Bessemer process chiefly owes its existence. In him the metallurgical world has lost a bright and useful ornament.

Sidney G. Thomas was born in April, 1850, and was educated chiefly at Dulwich College, with a view of entering the medical profession. His father's death, however, rendered this impossible, and at the age of seventeen he entered the civil service. Though his position was connected with the administration of the law, a legal training was not a necessity; but it is an illustration of the thoroughness which characterised him that he devoted a considerable time to the regular study of law, in order, as he thought, to be better qualified for his daily work. His predilections, however, lay in a scientific direction, and to chemistry and metallurgy he was specially devoted. Engaged during the day, his only opportunities of study were in the evenings. A small laboratory at home was the scene of much of his study, in which he obtained further guidance by attendance at the laboratories of Mr. Arthur Vacher, of Great Marlborough Street, and of Mr. George Chaloner, of the Birkbeck Institution. However, Sidney Thomas was really an outcome of the admirable system of popular scientific instruction organised by the Science and Art Department.

It was in 1870, while attending a course of lectures on metallurgy at the Birkbeck Institution, that the idea of dephosphorisation first took strong hold upon his mind. To use an ex-

\* For the matter of this obituary, the Editor is mainly indebted to the excellent article in *Iron*.

pression which at that time he was fond of quoting, "the man who eliminates phosphorus by means of the Bessemer converter will make his fortune"; and the commercial idea here expressed was quite as much in his thoughts as the scientific nature of the problem. In early conversation on the subject he frequently used to point out the product of a royalty of sixpence a ton on 3,000,000 tons annually of Cleveland pig. He proceeded in a strictly logical manner in the study of his chosen subject. Collecting all the data, both chemical and practical, he came to the conclusion, as Gruner had done, that the acid lining of the converter was the great enemy of dephosphorisation, and from this to the idea of a basic lining was a natural step. True, lime linings had been used in puddling furnaces before 1850. But the difficulty always had been to make them stand. Numerous experiments appeared to show that a small admixture of silicate of soda with lime, or magnesium lime, or Portland or Roman cement, would give good results, and about 1876 Thomas obtained the able assistance of his cousin, Percy C. Gilchrist, who was then chemist at the Cwm-Avon works, but soon after went to Blaenavon, where an immense number of experiments was tried. He systematically theorised and planned experiments, keeping up a continual correspondence with his cousin, who carried them out, besides working independently and conferring with him. His brief occasional holidays were spent in running down to South Wales and supervising the more important ones, and it was on one of these scientific journeys that the seeds were sown of the lung weakness which enfeebled his later years. In November, 1877, Thomas took out his first patent, the complete specification being filed on May 21 subsequently. Events, however, moved with him so quickly that in July 2, 1878, he says: "I regard it as somewhat out of date," and, as a matter of fact, patent succeeded patent up to the present year.

Matters up to this time had, of course, been kept very secret. He had but two or three confidants, but the need for experiments on a larger scale led him to seek the aid of Mr. Martin, the manager of Blaenavon, who enabled the experimenters to work with converters holding as much as half a ton, while at Dowlais, through the courtesy of Mr. Menelaus, a few blows were made with a 5-ton converter. On March 28, 1878, the first public announcement was made to the Iron and Steel Institute. Mr. I. Lowthian Bell had read a paper on the separation of phosphorus from pig-iron in a furnace lined with oxide of iron. Sidney Thomas was present as a visitor, and during the discussion made the following memorable remarks: "It may be of interest to members to know that I have been enabled, by the assistance of Mr. Martin, at Blaenavon, to remove phosphorus entirely by the Bessemer converter. Of course, this statement will be met with a smile of incredulity, and gentlemen will scarcely believe it, but I have the results in my pocket of some hundred and odd analyses by Mr. Gilchrist, who has had almost the entire conduct of the experiments, varying from the very small quantity of 6 lb up to 10 cwt., and the results all carry out the theory with which I originally started, and show that in our worst

cases 20 per cent. of phosphorus was removed, and in our best I must say that 99.9 was removed, and we hope we have overcome the practical difficulties that have hitherto stood in the way."

It may be mentioned in this place that, although several persons worked at basic processes before Thomas, not a ton of metal was made by such processes before 1878. Then Thomas devoted his life to it, and, in 1884, 864,000 tons were made. His foreign patents proved a source of great profit, while in England but a small return has been made. The United Kingdom as a whole has contributed a mere trifle to the money rewards of the inventors of the basic process.

The exertion of constant travelling, combined with the anxiety of perpetual work, ultimately, however, ruined Thomas's health, which was never very robust. In 1882 he was ordered to pass the winter in Australia, whither he went via India, and returned through the United States. On this journey, however, he did much work, and came back in the early summer as full of ideas as ever. He only stayed in England a few months, and in September left again for Algeria, tended by an affectionate mother and sister, who had broken up their home to solace his exile. At Bir el Droadj he set up his habitation, including a laboratory, and worked away at the utilisation of phosphoretic slag and other problems. Last summer he moved north to Paris, where he submitted himself to a method of treatment which promised good results, but the improvement was only apparent, and the busy brain ceased its labours on the morning of Sunday, February 1.

Sidney Gilchrist Thomas was a man of high moral worth, and great amiability and kindness. Though never married, he was the central figure of a happy family, comprising a widowed mother, an only sister, and a younger brother. When success could no longer be denied him, he received the highest honours among metallurgists, but he received them with true modesty.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

*Improvements in Filter Presses.* B. H. Remmers, Glasgow. Eng. Pat. 2978, February 8, 1884.

The object of this invention is to facilitate the ligation of the solid matter collected in a filter-press before its removal from the apparatus. Instead of forming the channels which convey the washing water to the interior of the press in projecting portions or lugs outside the chambers, the patentee forms them in the corners of the chambers, such ducts being formed by the immediate contiguity of holes formed in the rims of the plates. The ordinal numbered chambers communicate with one passage so formed by means of small T-shaped cores, and the cardinal numbered plates communicate with the other passage by similarly shaped cores. Any liquid admitted into the chambers by one of these passages can only leave the apparatus, when the ordinary outlet cocks are shut, by the other channel, to arrive at which, the liquid must in its course pass through the chambers and their contents, and thus removes the soluble constituents in its passage. The patentee claims as novel the construction of the passages, as described, in the corners of a filter-press chambers for the purpose set forth.—C. C. II.

*An Improved Compound for the Prevention of Incrustations, and of Galvanic Actions in Steam Boilers.* M. A. F. Mennons, Paris. Communicated by R. de Martino, Meta Sorenta, Italy. Eng. Pat. 3614, February 20, 1884.

THE improved compound consists of a mixture of chloride of lead, valonia, and chloride of ammonium, with the addition in some cases, when required, of carbonate of soda, or some compound capable of precipitating lime. The patentee divides waters into four classes, and in each case uses a mixture containing different proportions of the materials. The quantity added to the boiler varies, but generally in the proportion of about one quarter of an ounce per horse-power of boiler capacity per day. The claim is for a mixture for the purpose described, consisting of chloride of lead with organic products such as those specified, and alkaline salts.—C. C. H.

*A Method of and Apparatus for Purifying Feed-Water in Steam Boilers.* H. H. Lake, London. Communicated by G. Stollwerck, Cologne. Eng. Pat. 11,079, August 8, 1884.

THE object of this patent is to provide means for freeing the water from impurities in the interior of the boiler itself, thus preventing incrustation. A diaphragm, slightly convex, running the greater part of the length, and nearly touching the sides of the boiler, is fixed in its upper part just below the water line. A series of perforated subsiding boxes are formed on the upper surface of the plate in a double row, communicating at one end only. On entering the first box, near the front of the boiler, the water is met by the steam and boiling water of the apparatus, and forced through the perforated boxes along the whole series. During its passage the mineral matters separate out and subside, the water falling into the boiler at the end of the series comparatively pure. The subsiding boxes are periodically cleansed. The patentee embraces under three claims the method, apparatus, and mode of using the combination as and for the purpose substantially described.—C. C. H.

*Improvements in Filters.* Geo. Cheavin, Boston. Eng. Pat. 11,390, August 18, 1884.

A CYLINDRICAL vessel, having a flat bottom and a movable cover, is provided at about one-fourth its distance from the bottom, with a perforated partition upon which rests a series of filtering beds of animal charcoal of different degrees of fineness—coarse at the top and bottom of the series, and finer in the centre. A perforated cup is placed in the upper portion of the filtering beds containing sponge, secured in position by a porcelain disc, which also covers the charcoal, and is cemented down so that no water can pass into the filter without going through the sponge. The part above forms a supply chamber. An air tube is formed reaching from that part of the apparatus under the perforated diaphragm in which the filtered water is received, to the upper part of the cylinder, and can be made available for cleansing the filter by forcing water through it so as to pass upwards through the filtering beds. The patentee claims—(1) the filter as described; (2) the combination of the permeable beds and the perforated cup; (3) filters with compacted filtering beds as described, provided with an air tube which can be used in the manner described for cleansing the filtering beds.—C. C. H.

*A Combined Filter-Press and Montejus.* George Fletcher, Poplar, Middlesex. Eng. Pat. 11,440, Aug. 19, 1884.

IN order to economise space, and to use only one set of pipes and fittings, the patentee forms the montejeus or forcing receiver as a tubular casting by prolonging the outside rim of the filter-press head, and providing the end with a flange and cover. The supply pipe to the filter-press, the charging and air inlets are employed in the usual manner. The claims are—

- (1.) The combination of filter-press and montejeus.
- (2.) The method of working the filter-press by one set of fittings as described.—C. C. H.

*Method and Apparatus for Purifying Water for Use in Steam Boilers.* H. H. Lake, London. Communicated by G. H. Knott, Chicago, U.S.A. Eng. Pat. 11,661, August 26, 1884.

IN order to remove lime salts held in solution in a water free from carbonic acid, the patentee proceeds as follows:—A vessel is provided having an inlet pipe near its lower part, provided with perforation on its under side. The interior of this vessel is filled with lime, freshly burned, and its upper portion communicates with a second vessel provided with diaphragms alternately open at the top and bottom, the cells so formed being filled with straw, hay, or some such material, forming a filter. The whole body of the water is passed through the lime in the first vessel, and from thence through the filtering apparatus, whereby the salts precipitated from the water are filtered out and retained. The patentee points out that this method of purification of water differs from Clark's method, because the whole body of the water comes in contact with the lime in bulk, and thereby renders the operation more effectual, and demands less skill in carrying it into effect. The claims are—

- (1.) Treating water by passing it through lime in bulk succeeded by mechanical filtration.
- (2.) A lime vessel in combination with a filtering vessel.
- (3.) A lime vessel in combination with a perforated water supply pipe at its lower part.—C. C. H.

*An Improvement in Filtering Apparatus.* Johann Kroog, Halle-on-the-Saale. Eng. Pat. 12,520, September 17, 1884.

THE object of this invention is so to construct and use a filter press that homogeneous cakes are produced, and much of the difficulty of evenly and properly washing the cakes in the filter-press thereby removed. The corrugated surfaces of the plates do not terminate in deep cross drainage grooves as heretofore, which not only weaken the plates, but do not afford sufficient outlet for the filtered liquid; but are replaced by grooves formed in the joint surface of the lower part of the plate, which is made wider than usual. These communicate by several T-shaped cores with the drainage face of the plates, and at their outer ends with the passage leading to the efflux cocks or the closed conduit often formed for carrying away the filtrate, without exposure to air. The distance frames are fitted at their upper part with air cocks, and the channel for supplying the material to be filtered is arranged at the lower part of the filtering chambers. The method of working the press so as to obtain the improved effect is also described: the efflux cocks on the plates are closed at the commencement of the operation, and all the air cocks opened, until the air is displaced and the chambers are completely filled; the air cocks are then closed, and the efflux cocks opened, filtration proceeding as in the usual way. The claims are—1. The combination of the filtering plates and the outlet grooves as described. 2. The combination of the frames with an air cock. 3. The method and mode of working substantially as described.—C. C. H.

*Improvements in Compression Pumps for Condensable Gases.* S. Pulpett, Knowle. Communicated by S. Doran, Philadelphia, U.S.A. Eng. Pat. 13,917, October 21, 1884.

THE object of this patent is to prevent the escape of such gases as ammonia vapour during compression, and to provide an efficient metallic packing for the piston rod, thus avoiding loss of gas during the time that the packing was renewed as heretofore. Another part of the invention has reference to constructing the inlet and outlet valves, so that they can be moved on their seats, on which they are apt to stick, without taking them out of their places. In the front cover of the cylinder a bush is provided, through which the piston rod passes, and capable of adjusting itself to the inequalities of the piston rod and cylinder; in front of this there is a suitable metallic packing and a spherical washer bearing against the wall of a sealing chamber, which is filled with water, or else some suitable lubricant. In front of this, again, there is

a leather collar to prevent the escape of the sealing liquid, and a second row of metallic packing. The cylinder is thus able to be made perfectly tight to the atmosphere, notwithstanding the irregularities of the cylinder and piston rod. The valves are made with a screw cap, which can be removed when necessary without letting any of the gas in the interior of the cylinder escape, and can be moved up and down on their seats, and thus sticking is prevented. The various details of the improvements are covered by seven different claims.

—C. C. H.

## II.—FUEL, GAS, AND LIGHT.

*Recent Improvements in the Manufacture of Illuminating Gas and in Apparatus therefor.* Dingl. Polyt. Journ. 253 (11), pp. 467 and 472.

H. POLLACK, Hamburg (Germ. Pat. 26,170, 1883), carburets air by allowing gasoline to flow from a vessel A (Fig. 1) into the carburetter B, where it comes in close contact with air entering through the pipes M. The gas, thus formed, can be used for many purposes, but it is

FIG. 1.

preferable to remove not-gasified gasoline particles in a separate purifier. The flow of the gasoline is regulated by the valves C and E and the float F. The carburetter B receives on the false bottom N wool or any other material offering a large surface.

G. A. Schoth, London (Germ. Pat. 26,569, 1883), has patented an apparatus for carburetting air. The vessel A (Fig. 2) is divided in two chambers c and c by suspending an inverted funnel b from the top. The compartment

c receives the carburetting agent, whence it flows through the pipe g into c, a branch f keeping it at a constant level. Air enters the chamber c through i, becomes car-

buretted, and escapes through h, a sliding cap m regulating the degree of carburetting at will. In Fig. 3 the

Fig. 3.

lamp is provided with a pair of hand-bellows; the burner b sits immediately on the escape pipe l. Different shapes

Fig. 4.

Fig. 5.

Fig. 6.

Fig. 7.

of burners are represented by Figs. 4, 5, and 6. They are made of wire gauze of platinum or any other metal, or

of a fire-resisting material. For smaller lamps a single cap is sufficient (Figs. 4 and 5); for large ones a combination of several caps is required (Fig. 6). On lighting the lamp, the tap is only turned on a little, but as soon as the gas mixture is ignited, the tap is opened full-bore, whereby the gauze becomes incandescent without the formation of a flame.

F. A. Dieker, Hamburg (Germ. Pat. 26,333, 1883), recommends for enriching poor illuminating gas to fix at a certain point of the gas pipes *b* (Fig. 7) a branch with tap *c*, through which vapours of hydrocarbons are directly passed into the gas. The vapours are generated in a small copper boiler *A*, heated by the flame *a*, and provided with a safety-valve *d*.

To keep clear the ascension-pipes of gas retorts, A. Klönne, Dortmund (Germ. Pat. 22,703, 1883), cools the gas in the ascension-pipe so far as to condense even easily volatile substances, which thus wash the sides of the pipe, carrying any sediment back into the retort. With this view a water-chamber *w* (Fig. 8) is arranged

in the bend of the pipe. In order to retain in the retort solid particles, and not allow of their being carried to the exit-pipe, a series of perforated metal plates *b* is placed within the head of the retort as shown in Fig. 9.

Kunath (*Journ. für Gasbeleuchtung*, 1884, p. 262) publishes his investigation on the causes which produce thin or thick gas tar. He comes to the conclusion that

the nature of the tar depends upon the physical properties of the coal. If nut coals be gasified no thick is obtained, whatever the temperature may be at which the coal was distilled; the same coals, however, mixed with smalls and duff, will always produce a thick tar on distilling, even at a comparatively low temperature. The cause of a thick tar is principally the fine dust which is mechanically carried away to the exit-pipe and receiver. If a coal be used which is freed from all stuff passing through a 5mm. riddle, no thick tar can be produced, whatever the temperature may be. Small and dust must be worked up separately in a moist state or together with the double quantity of nut coals, with the precaution that the smalls are placed at the back end of the retort. Kohlstock and Jochmann, however, disagree with Kunath, and ascribe the formation of thick tar to a very high temperature of distillation.

The invention of L. A. Chevalet, Paris (Germ. Pat. 19,811, 1882), relates to an apparatus for purifying gas. Perforated shelves *c* (Figs. 10 and 11) divide the washing tower in several compartments, which are in connection with each other by the overflow pipes *c*. These dip in cups *e*, which on their part feed the partitions *c* with water. The gas enters the tower through *B*, and after

being thoroughly washed, it escapes at *H*. The washing liquor runs off at *z*. A manometer *t* shows the pressure in the different compartments, gas-tight dampers allowing of regulating the draught to a nicety.

The scrubber of A. Kühnelt, Barmen (Germ. Pat. 43,356, 1883), consists of several compartments arranged

above or beside each other, and provided with perforated drums of sheet-metal. The crude gas enters the bottom chamber *B* (Figs. 12, 13, and 14) through the pipe *a*, passes through the holes of the slowly revolving drum *c*, proceeds through *d* to the chamber *C*, and so forth until

it escapes, deprived of its tar and ammonia, through the pipe *k*. Water trickles into the top chamber *D*, overflowing at *n* and *m*, and leaving the scrubber through the syphon *z*.

phosphorus which they contain, and from the varying quantities of phosphorus in cannel, has arrived at the following conclusion:—That the spores which chiefly occur in that particular coal, and which are easily visible

fig 14.

fig 16.

The "Phonix Washer Scrubber" of G. Waller & Co., London, depends on the same principle as Kühnells. Partitions *a* (Figs. 15 and 16) divide it in several compartments in which cylinders, formed of wooden staves, revolve round a common hollow shaft. One half of the cylinders is always under water. The gas entering at *A* comes in close contact with the wet staves of the first drum, passes through the hollow shaft *B* into the second, and owing to the partition *c*, proceeds through the pipe *n* to the third, and at last escapes at *z*. The water travels through the apparatus in the opposite direction by means of pipes *v*.—S. H.

with a microscope, contain the principal amount of phosphorus. The following percentages were found:—

Coal from Commentry	0.00163	per cent.
"    Ferriere	0.00385	"
Cannel from Commentry	0.01260	"
"    Lancashire	0.02852	"
"    Wigan	0.02246	"
"    Newcastle	traces	"
"    Glasgow	0.00572	"

Hoghead coal from Autun	traces	"
"    "    Frioul	0.06276	"

—J. C

On the Origin and Distribution of Phosphorus in Coal and Cannel. Ad. Carnot (Compt. Rend. 99, 154).

THE author has experimented on a large number of different kinds of coal with respect to the proportion of

Composition and Properties of Coal with relation to its Vegetable Origin. Ad. Carnot (Compt. Rend. 99, 253).

THE author has determined the composition and the action of heat with various samples taken from the coal-

beds of Commentry, the vegetable origin of which has been definitely ascertained. This has been carried out with a view of proving that not only the quality of the coal, but the nature of the original plant, exercises an influence. For in the same coal-bed the cause of all outward qualities, such as age, &c., must be identical. From the author's experiments it appears that the elementary constituents of the coal are closely allied; on the other hand, the amount of volatile products, the coke and its outward appearance on heating very dissimilar.—J. C.

*On Lighting with Oil-Gas.* By Shaar. Chem. Zeit. 60, viii, 1877.

THE author gives first an historical account of gas lighting, mentioning several investigators, such as Shirley, Lowther, Becher, Hales, and Claytons, and their works. Oil-gas was first introduced in Hull, Liverpool, and some other towns, but was soon given up, partly on commercial grounds and partly on account of the inefficiency of the apparatus. It is only within the last twenty years, and since the apparatus has been greatly improved by Hirzel, Riedinger, Drescher, Pintsch, Suchow, and others, that lighting with oil-gas has had a greater diffusion, and is still only to be recommended, in cases where the number of burners is limited. While formerly principally animal and vegetable fats were used, mineral oils or their waste products are now almost exclusively used. The oils which are best suited to gas manufacture are shown by actual experiment to be those having a specific gravity of 0.65 to 0.86. The amount of gas obtained is on an average of 45 to 60cb.m. of gas per 100kg. oil. The petroleum gas-oil of Artmann, of Brunschwieg, yields 65 to 70cb.m.

Hirzel used his so-called ball retort, Hubner a standing slightly conical one, and Pintsch used two  shaped, which lay one above another, and which were connected. The temperature must be about 900° to 1000° C.; at a higher temperature a part of the gas is decomposed in the retort, by which a loss is sustained both of quality and quantity; if the temperature is too low, a part of the oil is carried away unconverted, which stops up both purifying apparatus and the pipes, besides making the gas give off soot. The oil is stored in receivers above the furnaces, from which it flows in a fine continuous stream into the retorts. The success of the manufacture depends upon the regulation of the proportion between the flow of the oil and the heat of the retorts. A great advantage of oil-gas over coal-gas is that it does not alter by being kept, whereas coal-gas suffers marked deterioration within 24 hours. The supply pipes can be much smaller than with coal-gas, because the same amount of light is produced with less gas. The burners must have very small openings, and the gas pressure must also be very small. To Pintsch is due its introduction for the lighting of railway carriages; it has also been used with success for the lighting of buoys. From the author's calculation of cost it appears that 1cb.m. costs 4.92 penny (41.24pf.). Supposing the consumption of one flame to be 30l. per hour, the cost will amount to 0.15 penny (14pf.); as against 120 to 150l. the consumption in one coal-gas burner of equal illuminating power, which at a price of 20pf. per 1cb.m. gives 0.28 to 0.36 of a penny (2.4 to 3.0pf.).—F. T. S.

*Improvements in Apparatus for the Purification of Gas.* T. N. Kirkham, D. Hulett, S. Chandler, and J. Chandler, London. Amended Specification of Eng. Pat. 422, February 1, 1877.

A VESSEL of cylindrical or other suitable form is placed horizontally, and divided into a number of compartments by plates decreasing in height from the end where the gas makes its exit to the opposite end. Inside, and running the length of the main vessel, is a shaft working in stuffing boxes and fitted with sets of concentric or other tubes, or with a valve or louvres, each set working in one of the compartments above mentioned. Clean water is admitted as near the gas outlet as possible; gas is passed in at the other end and the shaft is made to revolve. This causes the tubes or their equivalents

repeatedly to dip in the liquor, so that a wet surface is constantly being exposed to the passing gas. The arrangement of the division plates causes the water to flow in the opposite direction to the gas, which is also at its entrance brought into contact with the most concentrated portions of the liquor.—A. R. D.

*Improvements in Purifying Gas.* T. N. Kirkham, D. Hulett, S. Chandler, and J. Chandler, London. Amended Specification of Eng. Pat. 1814, May 10, 1877.

THIS is an improvement upon the invention mentioned in English Patent 422, February 1, 1877. The apparatus consists of the outer vessel therein referred to having, inside, a number of thin metal plates arranged to meet the gas edgewise and carried upon a shaft. This shaft being made to rotate, immerses the plates in the washing liquor contained in the vessel, and thus constantly exposes a wet surface to the gas. Drums of loose wire-work filled with light scrap iron may be substituted for the arrangement of plates. If more than one drum or set of plates is used, the outer vessel is divided into a corresponding number of compartments, the division plates being set at such different levels as to cause the liquor to flow in the opposite direction to the gas.—A. R. D.

*Improvements in Apparatus for Condensing, Washing, and Purifying Gas.* T. N. Kirkham, D. Hulett, S. Chandler, sen., and S. Chandler, jun., London. Amended Specification of Eng. Pat. 4928, December 29, 1877.

THIS specification refers to improvements upon the invention mentioned in English Patent 1814, May 10, 1877. Inside the outer casing is a central horizontal shaft, upon which are arranged clusters of annular plates kept a small distance apart from one another by washers to allow the passage of the gas between them. Each cluster of plates works in a separate chamber, and the arrangement is such that the gas traversing the apparatus enters each chamber from the preceding one at the central space round the shaft, and passes between the annular plates to their outer peripheries, whence it is again drawn to the centre to enter the next chamber. The lower portions of the chambers contain water, or other suitable liquid, in which the annular plates dip as they revolve, and which, by the disposition of the levels of the partition walls, is caused to flow through the apparatus in the opposite direction to the gas. The original specification allowed the substitution of perforated discs for annular plates.—A. R. D.

*Improvements in Apparatus for Coking and Distilling Coal.* C. E. Bell, Durham. Eng. Pat. 443, January 2, 1884.

ACCORDING to this invention the walls of the coking oven, instead of being built solid, are provided with flues perforated for the admission to them of vapours from the body of the oven. The flues are preferably horizontal, and situated below the highest point to which the oven is charged. They are connected with a fan or exhauster, from the action of which they can be shut off at will by means of valves. When the oven is in operation the gaseous products are drawn off by the exhauster through these flues, and caused to pass through suitable scrubbers and condensers. The uncondensed portions are returned to the oven to be burned there. This arrangement of wall flues may be worked in connection with the plan of bottom apertures followed in the Jameson process.—A. R. D.

*Improvements in Apparatus for Washing and Drying Coal and other Substances.* C. E. Hall, Sheffield. Eng. Pat. 677, January 4, 1884.

THIS apparatus is for freeing small coal, or other substances, from dirt or other impurities of different specific gravity. The coal is fed through a hopper into a trough, a stream of water playing upon it as it falls. This trough

is provided with a series of settling pockets for the dirt, placed before division boards or weirs. At each settling pocket is a bye-pass trough, to divert the stream of water when the pocket is to be cleaned out. From the trough the clean, wet coal is delivered on to a perforated plate, covering a deep settling tank. The coal is worked over this plate by a creeper into trucks or other suitable receptacle. A pump draws the water out of the settling tank, and passes it once more to the hopper end of the apparatus, to be used over and over again. The suction of the pump is intended to draw air through the perforated tank, and so partially dry the coal thereon. The finest particles of coal pass through the holes in the plate, and are deposited in the settling tank. The pipe conducting the water from the pump to the hopper is situated underneath the washing trough, and is connected with the dirt pockets by suitable valves, so that these can be flushed at will to stir up the contents and lift up to the surface any coal that may have settled therein.—A. R. D.

*A New or Improved System of, and Apparatus for, Supplying Air for Combustion with Gas.* Thomas Thorp, Whitefield. Eng. Pat. 962, January 8, 1884.

This invention consists in supplying air under a pressure greater than that of the atmosphere to the gas as it issues from the burners. In the case of ordinary downward burners, it is forced through a jacket surrounding the gas supply pipe, and so led to impinge upon the flame that it is possible by this means to burn gas under very low pressure in a downward flame. In the case of regenerative burners, the air is passed through the regenerator, and produces the same effect, also removing the necessity for using globes or chimneys. The air draught is obtained by any suitable apparatus. One method is to drive air or steam at high velocity through a nozzle, in a pipe provided with openings to admit air, thus inducing a current after the manner of an injector.—A. R. D.

*A New or Improved Appliance to Gas Retorts for Preventing the Obstruction of the Ascension-Pipe.* C. D. Abel, London. Communicated by A. C. Niemeyer, Deventer, Holland. Eng. Pat. 1195, Jan. 10, 1884.

To the underside of the bonnet or cover on the retort there is fastened by hinged joints a disc of such configuration as nearly to fit the sides of the retort, leaving between the two only a narrow interstice, through which the gas from the retort must pass on its way to the ascension-pipe. This disc being kept somewhat cool by its connection with the outer cover, a great deal of tar condenses, and small coal settles out thereon, which would otherwise have passed on to the ascension-pipe, and in time have blocked it up.—A. R. D.

*Improvements in Apparatus and Process of Purifying Gas.* A. W. L. Reddie, London. A Communication from the Smith and Sayre Manufacturing Co., New York. Eng. Pat. 2341, January 29, 1884.

ORDINARY scrubbers, consisting of upright chambers filled with stationary scrubbing surfaces, are connected together in pairs, the connections being made in the lower portions so that the gas passes down the one scrubber and up the other. Of course any number of pairs may be worked in a series. The chambers are also connected at the bottom by overflow-pipes, arranged at such levels that the washing liquor is continually making its way through the series of scrubbers in the opposite direction to the gas. A double-acting pump—one being required for each pair of scrubbers—pumps the liquor from the bottom to the top of the chambers, discharging it through a pipe perforated on the upper side, so that it strikes against the top of the scrubber, and, being beaten into spray, is more evenly distributed among the scrubbing surfaces. A new kind of scrubber, forming part of the invention, consists of an upright chamber filled with inclined rows or tiers of parallel tubes, through which a frigorific liquid is circulated. The exterior of these tubes form the condensing and scrubbing surfaces. The tube

system is continued to the bottom of the chamber into the receptacle for the washing liquor, which is thus the more effectually cooled. Pipes are also arranged outside the scrubber for the cooling of the adjacent atmosphere by the circulation of the frigorific liquid. These scrubbers are to be arranged and worked as those described above.—A. R. D.

*An Improved Arrangement of Air and Smoke Passages in the Setting of Retort and Muffle Furnaces.* A. W. L. Reddie, London. Communicated by the Stettiner Chamotte Fabriks-Actien Gesellschaft vormals Didier, Stettin. Eng. Pat. 8144, May 23, 1884.

ACCORDING to this arrangement the products of combustion, after having passed uniformly through the furnace, are brought downwards and used for preheating the air necessary for combustion—the said air entering by passages contiguous to the smoke flue. These passages are so provided with outlets that only a portion of the total air admitted enters below the fire-grate. The rest enters the furnace at a point where it can be profitably employed to complete the combustion. The quantities of air admitted at each place are controlled partly by slides and partly also by the depth of fuel in the fire-grate. Below the grate is situated an iron water tank, under which the escaping hot gases pass on their way to the chimney. The steam thus generated, besides having a preserving effect upon the fire bars, produces a further supply of fuel by its decomposition in the fire.—A. R. D.

*Improvements in the Manufacture of Gas.* S. C. Salisbury, New York. Eng. Pat. 9065, June 17, 1884.

This is an invention for the manufacture of illuminating gas from hydro-carbon oils and hydrogen, or from coal and hydrogen. The principle may be applied to ordinary gas retorts. During the first part of the distillation, when the richest portions of the gas are coming off, and (by the ordinary process) the bulk of the tar is condensed, hydrogen is supplied to the retorts. This reduces the gas to the desired quality, while the valuable hydro-carbons, which would otherwise be condensed as tar, go to form a fixed gas. At the end of the distillation, when the gas is of the poorest quality, it is enriched by the addition of hydro-carbon vapour. The hydrogen is generated by passing superheated steam over heated scrap iron, and is carried by a pipe to the rear of the retort. The same pipe may serve for the introduction of the hydro-carbon vapours later on. When the gas is to be made from hydrogen and oil without coal, the pressure of the superheated steam behind the hydrogen is made to drive the hydro-carbon vapour through an injector into a chamber where the gases are thoroughly mixed and re-heated.—A. R. D.

*Improvements in Furnaces for Use in the Manufacture of Gas.* W. P. Thompson, Liverpool. Communicated by the Stettiner Chamotte Fabrik-Actien Gesellschaft vormals Didier, Stettin. Eng. Pat. 10,090, July 12, 1884.

The channels of the regenerator, grouped on the right and left of the furnace, are so arranged as not to weaken the foundation of the centre of the setting. The air inlet passages between the regenerator channels are constructed to admit the air only at the upper part of the furnace, so that the heat is developed more gradually, and retained long enough to raise all the retorts to a uniform temperature. On each side of the furnace, closed wrought-iron steam-generating vessels are disposed above the flue conducting the waste gases to the chimney, and so arranged as to be easily replaceable. The generator has double walls, between which the air that it requires is heated before it reaches the grate. Here the air inlets are situated in a row, just above the steam jets, so that a perfect mixture of air and steam enters the grate. The steam generating vessel is provided inside with a box, closed at the top but open at the bottom, and communicating with an escape pipe outside. When the water level is too high, the excess flows away

by the escape pipe, while steam blowing out from the latter warns the fireman of a deficiency of water. An exhaust pipe conducts the steam to the grate. A special arrangement for the automatic regulation of the water supply consists of an iron vessel, communicating, by a pipe at the bottom, with the water inlet pipe of the steam generator. In this vessel is a hollow tinplate box, carrying a rod with a conical valve at the top, which closes the water supply. The tinplate box rising or falling, according to the water level in the steam generator, admits or cuts off the supply as required.—A. R. D.

*Improvements in the Process of obtaining Ammonia from the Gases evolved from Blast Furnaces, or from the Gases produced from the Destructive Distillation of Coal, Shale, or other Carbonaceous Substances, and in the means employed therefor.* R. Main and W. Galbraith, in the County of Ayr, Scotland. Eng. Pat. 10,448, July 22, 1884.

THE ammoniacal gases from the products of combustion evolved from smelting or blast furnaces, and retorts or other apparatus used in the distillation of coal, are directed into a large tank or tower made of a material impervious to the action of hydrochloric acid. The tank or tower contains an aqueous solution of hydrochloric acid, which may be injected into the same either in the form of spray or otherwise. The acid in falling to the bottom of the tower carries with it the ammonia present in the gases. The resulting solution is used over and over again, until it is sufficiently saturated with ammonia. In making ammonium sulphate from this solution of ammonium chloride, the latter is treated with lime, magnesia, or other alkali, and the ammonia which is driven off is saturated with sulphuric acid in the usual manner.—D. B.

*Improvements in the Manufacture of Artificial Fuel.* E. Johnson, West Cowes. Eng. Pat. 6556, August 29, 1884.

THREE measures of coal dust and half a measure of powdered chalk, moistened, intimately mixed, and pressed in moulds of size and shape as required, yield a fuel for

is fed by a bucket, and, below this, a generating chamber round the outside of which is arranged a set of burners. There is also a gasholder, which is so connected with the gasoline feed apparatus that the distributing chamber is supplied only when the volume of gas in the holder is small. The gasoline exudes from the distributing chamber by small openings therein into the generator below, and is there vaporised by the external heat of the burners. From here it passes through an injector (by means of which it draws atmospheric air along with it) into an intermediate chamber, and thence to the gasholder. The expansion and contraction of the generating chamber is made to effect the automatic regulation of the burners surrounding the said chamber.—A. R. D.

*An Improvement in Furnaces for Burning Small or Moist Fuel.* C. D. Abel, London. A Communication from G. Alexis Godillot, Paris. Eng. Pat. 3355, 1884.

THIS invention relates to modifications of the furnaces referred to in English Patents 1769 and 3839 of May 2, 1878, and September 3, 1881, respectively. The furnace chamber is fitted with a sloping or semi-pyramidal fire-grate, upon which the fuel, delivered in at the top of the furnace, falls and burns, passing on meanwhile to a horizontal grate situated a little below the lower edge of the sloping grate. The space between the two grates allows for the insertion of a rake. The products of combustion pass away by a flue provided with a pocket for the settling out of dust, etc., and, to ensure a perfect combustion, receive on their way an additional supply of air heated by passing through suitable passages in the brickwork.—A. R. D.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*On the Manufacture of Lubricating Oils.* J. Ljutyk. Dingl. Polyt. Journ. 253 (11), pp. 460-467.

IS one of the largest petroleum refineries at Baku the following process is employed for the manufacture of lubricating oils. The petroleum residues after driving

which it is claimed that when used in combination with ordinary fuel it absorbs the smoke, engenders a greater heat, and prevents the formation of clinkers.—A. R. D.

*Improved Apparatus for the Manufacture of Gas.* A. M. Clark. A Communication from A. Henning and T. Henning, Sacramento, California. Eng. Pat. 12,481, September 16, 1884.

THIS apparatus consists mainly of a tank for holding gasoline, a distributing chamber into which the gasoline

off all kerosene are run into large storage vessels, placed in the ground and large enough to hold at least 1640 tons of residues. They are then pumped into tanks high enough to allow of sufficient fall into the stills. In the tanks they are heated by a steam-coil to 70° C., whereby water and other impurities collect at the bottom, whence they are run off from time to time. After this preliminary preparation they pass through the heater V (Fig. 1) into the still A. This has the shape of a horizontal cylinder and holds 8000kg. residues, which are driven off in 24 hours.

By means of a furnace with waste oils as fuel, the contents of the still are heated to about 160° C., when the distillation is assisted by overheated steam. The vapours escape at D, and are condensed in the cooling worm K, made of iron or leaden tubes. Sometimes bent cast iron pipes, *m, l*, allowing of the withdrawal of any condensed oils by a branch at the bottom, are interposed between still and cooling worm. The end of the latter is always carried through the wall to the receiver *p*, whence all uncondensed gases escape into the chimney. Where air and water cooling is combined, a partial separation of oil and water already takes place in the pipes *m, l*. The residues of the still sometimes serve as fuel. Besides horizontal, there are also vertical cylinders in use, provided with an arched top, and holding about 3200 kg., which are driven off in 12 hours. As regards the distillation itself, it is carried out differently in different works. Usually, when the distillate stands at 0.915-0.920, the outside heat is withdrawn and the operation finished by means of overheated steam until only little oil comes over. The still is then allowed to cool for two to three hours and the residue (goudron or degout) is run off into tanks placed outside the building. If a larger yield of heavy oils be required, the distillation is interrupted as soon as the distillate stands at 0.912. After allowing the still to cool for some time, fresh oil is run into it without discharging the residues of a previous operation, and after heating the contents to 160-180° C. the distillation is carried on as described above. In this manner an oil is obtained which is rather viscid.

To refine the first distillate, any water is removed from it by means of hand-pumps, and the oil is then fractionated. The first fraction has a spec. grav. of 0.865, the second 0.875. Both are useless for lubricating purposes. The former is sold as gas oil, the latter to cloth mills for oiling wool. The fraction between 0.885 and 0.895 is separately collected and is an excellent lubricating oil, known by the name of spindle oil. The fraction having a spec. grav. of 0.895 to 0.910, is first-class machine oil; that higher than 0.910 is cylinder oil, which is sometimes mixed with the machine oil to raise the density of the latter. If a higher fraction begins to separate solid matter at common temperatures, it is separately collected and mixed with spindle oil, whereby second-class machine oil is obtained. In order to make isabonaphtha or mineral machine fat, melting at 35° C., the residues of the still (degout) are mixed with the fraction of 0.865 spec. grav. in the proportion of 3 to 1, and very slowly heated in a still to 180-200° C., when the distillation is started by overheated steam. The fraction below 0.915 spec. grav. is of no use, but very soon a sample of the distillate separates on cooling, a solid matter which gradually increases until the whole mass solidifies at common temperatures. The distillation is continued until  $\frac{1}{3}$  of the charge has come over, when after cooling for 3 hours, the still is refilled without running off the residue. After heating up the contents, the distillation is carried on as far as possible. A second charge of degout and light oil (0.865) is then run into the still, and the distillation repeated as mentioned above. The still must be cleaned at the end of every second operation. Original naphtha residues yield up to 12 per cent. of isabonaphtha. All fractions have at first a dark yellow colour and a characteristic disagreeable smell, but after purification with sulphuric acid and repeated distillation they become transparent and lose their smell. The treatment with acid takes place in lead-lined iron cylinders with conical bottom, the mixing being brought about by an air-blast. The end of the reaction is reached, when a glass-plate dipped in the oil shows many black flakes on its surface. The quantity of sulphuric acid varies from 5 to 10 per cent. of the weight of the crude oil, according to quality. The oil is clarified by settling in lead-lined wooden tanks. After one or two days the clear liquor is pumped into the mixing vessels and neutralised with slaked and sifted lime, of which so much is gradually added until the oil turns light-yellow and has a faint alkaline reaction. It is then run into the settlers and warmed to 70° C., whereby the gypsum quickly collects at the bottom. On account of the fineness of the precipitate, the oil must be, however, filter-pressed. It is then redistilled in vertical

cylinder-retorts and collected in different fractions. The receivers have a contrivance to heat the oil up to 130° C., in order to evaporate traces of water which cannot be removed by settling. The residues of this second distillation, after cooling, are sold as waggon oil. The substance sold to cloth mills is refined in the same manner as the better class of oils, except that the neutralisation of the sulphuric acid is performed with dry potassium carbonate, of which so much is added as to give the oil a distinct alkaline reaction. For refining oils without a second distillation the crude oil is treated with sulphuric acid, neutralised with potassium carbonate, and after settling heated in iron pots to a boil, and lastly washed with hot water. The purification of mineral machine fat (isabonaphtha) is done in the same manner, but the oil is warmed to 80° C. before the addition of sulphuric acid. The settlers must be in a warm room or provided with a steam coil, since the mass solidifies at common temperatures. To raise its density, 0.5 to 1 per cent. of molten ceresine is added to the mass while still liquid.

—S. 11.

*Process for Working up Gas Liquor and Products from Gas Purification.* Dingl. Polyt. Journ. 252, 476.

In order to convert the whole of the ammonia in gas liquor into ammonium carbonate, Seidler (Ger. Pat. 26,633, August 9, 1883) distils the liquor over limestone, dolomite and similar substances. Thus the non-volatile ammonium salts are decomposed, e.g.—

The resulting ammonium carbonate contains some ammonium sulphide. It is therefore treated in concentrated aqueous solution with carbonic anhydride, and the precipitated ammonium carbonate is separated from the

mother liquor and converted into commercial ammonium carbonate by sublimation. The carbonic anhydride which escapes during this operation is passed into fresh portions

of ammonium carbonate solution, whilst the mother liquor is treated with sulphuric acid and worked up into ammonium sulphate. In working the process the gas liquor is pumped through the pipe *d* (Fig. 1) into the cooling vessel D in order to run through the pipe *e* into the heater B, thence through *f* into the spreading tube *g*, from which it descends through the charge of limestone contained in the cylinder A. Steam is introduced into A through the pipe *a* under the perforated bottom *b*. The non-volatile ammonium salts are split up into ammonium carbonate which escapes with the steam and into the corresponding lime salts, so that the liquor on its arrival at the bottom of the cylinder is free from ammoniacal compounds. It is carried away by passing through an automatic steam trap *c*. The vapours of ammonium carbonate are partially freed from water in the heater B, and simultaneously heat the gas liquor which flows through B, after which they enter into the condenser C. The supply of water is regulated so that the vapours leave the condenser at a temperature of 65°, and are condensed into a concentrated solution of ammonium carbonate by passing through the coil in D. The solution, after filtering through the bed of coke in E, is collected in the tank G. The absorption cylinder F is now filled with liquor from G to a certain height, indicated by the gauge glass *s*, and carbonic anhydride forced into the cylinder through the perforated pipe *o*, which is provided with branch pipes. The carbonic anhydride is obtained partly by decomposing the mother liquors from the ammonium carbonate with sulphuric acid, but mainly from the gases given off in the manufacture of ammonium sulphate. A portion of the charge in the cylinder is now run off through *r* and the deposit of bicarbonate separated from the mother liquor, washed with water and dried at a gentle heat, or converted into ammonium carbonate by sublimation in apparatus of the ordinary construction. Every time a portion of the charge is let off from F, fresh ammonium carbonate liquor is allowed to enter the absorption cylinder from the tank G. The carbonic anhydride which escapes from the cylinder F passes through the charge of coke in the tank E, which is provided with a false bottom, and it is partially absorbed by the descending stream of ammonium carbonate. That portion which escapes at *t* is conducted to a tower filled with coke and fed with sulphuric acid, where any traces of ammonium bicarbonate which may have been carried away mechanically are absorbed. The concentrated solution of ammonium carbonate is transferred to a horizontal cylinder provided with an agitator (Fig. 2)

and treated with carbonic anhydride, which is pumped in through the pipe *x*. The valve at *x* is left open until carbonic anhydride begins to pass through, when it is closed. The agitator is then set in motion, and carbonic anhydride forced into the cylinder until a pressure of five atmospheres has been reached. At first the carbonic anhydride is absorbed rapidly, afterwards the rate of absorption diminishes, the saturation being completed when the pressure, as indicated by the gauge *y*, remains constant after the working of the pump has been stopped. The liquor is then run off at *z*, and the ammonium bicarbonate separated from the mother liquor in the usual manner. For the recovery of ferrocyanides from products of gas purification Kunheim and Zimmermann (Ger. Pat. 26,584, July 6, 1883.) desulphurise the products in the usual manner and remove the soluble ammonium salts by lixiviation with water. The resulting mass is then dried in the air, mixed intimately with dry caustic lime in powder agitated in closed vessels and heated to from 40 to 100° to expel the insoluble ammonia. The product after extraction with water, yields calcium ferrocyanide liquors. The mixture after treatment with caustic lime may be first lixiviated with water, when an ammoniacal solution of calcium ferrocyanide is obtained. This is carefully neutralised and heated to boiling. An insoluble ferrocyanide compound is precipitated, which is mainly

composed of the double ferrocyanide of calcium and ammonium,  $\text{Ca}(\text{NH}_4)_2\text{Fe}(\text{CN})_6$ . This on treatment with caustic lime in closed vessels is decomposed, the liberated ammonia being collected, whilst a solution of pure calcium ferrocyanide is obtained. This solution is worked up into Berlin blue by precipitation with protoxide salts of iron and subsequent oxidation. For the preparation of potassium ferrocyanide the liquors are converted into potassium calcium ferrocyanide  $\text{CaK}_2\text{Fe}(\text{CN})_6$  by evaporating and treating them with the requisite quantity of potassium chloride. The deposited double cyanide is separated from the mother liquor, washed with water, and converted into potassium ferrocyanide by boiling it with a solution of potassium carbonate. For the formation of potassium ferrocyanide according to this method only half the usual quantity of potassium carbonate is required, the other half being supplied by potassium chloride, the cost of which is much less.—D. B.

*Investigations on Thiophene Derivatives.* R. Nahrnsen.  
Berichte d. d. Chem. Ges. 17, 2197.

SOME time ago the author obtained dithienyl by passing thiophene through red-hot tubes. In the present paper, the analyses of the freshly-prepared substance have been repeated, and the results confirm the previous formula—

Dithienyl yields, on heating with concentrated sulphuric acid, a sulphonic acid; and by the action of bromine a perbromodithienyl. Dithienyl melts at  $83^{\circ}\text{C}$ ., and boils constantly at  $266^{\circ}$ . It may be distinguished from thiophene by the action of concentrated sulphuric acid, which dissolves the former with a reddish brown colour in transmitted light, and with a deep green tint in reflected light. On pouring the solution into water the unaltered substance separates out. Thiophene, on the other hand, forms, with sulphuric acid, a pasty mass.—J. C.

*Action of Chlorine on Boiling Benzene.* R. Schüpphaus.  
Berichte d. d. Chem. Ges. 17, 2256.

THE compound described by Mennier (*Compt. Rend.* 98, 436) had already been prepared by the author, and formed under the name of diphenyldodecachloride, the subject of a crystallographic investigation by Dr. Seiling. It is obtained in the preparation of hexachlorobenzene, and crystallises out with that substance in the form of octahedra. These octahedra can be readily separated with a pair of forceps from the large tabular crystals of hexachlorobenzene, or, better, by the method of Mennier, with alcoholic potassium cyanide. Pure recrystallised benzene gives the same body. From the analysis, the author considers the formula to be  $C_{12}H_{10}Cl_{12}$ , formed by the union of two molecules of hexachlorobenzene and the elimination of two atoms of hydrogen, an opinion which the high melting point (above 290° C.) seems to confirm.—J. C.

*Comparison of the Methods of Fractional Distillation.*  
Hans Kreis Ann. 224, 259.

THE author has fractionated mixtures of low boiling points (benzene and toluene), as well as those of high boiling point (benzoic acid and naphthalene), with the different forms of apparatus hitherto in use, and has published the following results:—For low boiling liquids the best fractionating apparatus is that of Henpel (*Zeitschr. Anal. Chem.* 20, [4]); next in order comes Linnemann's, with wire-gauze partitions. With the glass-bulb arrangement of Wurtz, six distillations are as efficient as twelve made without the bulbs, and two bulbs have the same effect as four. For substances of high boiling point fractionating with glass bulbs is decidedly preferable to employing a long necked vessel.

*Improvements in Apparatus for Carbonising Sweetst, Bagasse and Similar Substances, and for Condensing the Vapours of Distillation.* Communicated by J. A. Mathieu, of Detroit, United States of America. W. P. Thompson, Liverpool and London. Eng. Pat. 5049, June 17, 1884.

This invention is not suitable for abstraction without the drawing accompanying the specification.—D. B.

*Improvements in Apparatus for the Distillation of Solid Substances.* B. P. Walker, Moseley; and J. A. Beresford, King's Heath. Eng. Pat. 2433, January 31, 1884.

This specification relates to improvements in a former patent. Retorts are arranged in pairs axially coincident, with a passage between the ends, two or more being placed in a row. The interiors of the retorts are fitted with a screw, the one of each pair being right-hand, the other left-hand, so that the thrust blocks before found necessary are not needed. The screws are driven by means of worms and worm-wheels, each worm being of an opposite hand to that immediately next to it on either side, so that all end thrust upon the driving-shaft, which would ensue if the worms were all of the same hand, is avoided. The retort screws may also be made in some cases of an increasing pitch; for instance, in the case of those materials which expand considerably during distillation, so as to avoid jamming or blocking; and in other cases the pitch may be made diminishing so that the material is compressed during distillation, which is found desirable with materials of a light nature. The patentees claim—(1) the arrangement of propelling screws in the retorts end to end, and of an opposite hand in the pitch; (2) the arrangement of the retorts in parallel rows, so that the thrust of the driving worms may be neutralised; (3) the construction of the main screws with an increasing or diminishing twist as described; (4) the arrangements of retorts as described.—C. C. H.

#### IV.—COLOURING MATTERS AND DYES.

*Process for the Recovery of Aniline from Waste Liquors.* Dingl. Polyt. Jour. 253 (11), p. 479.

F. GRÄSSLER, Camstatt (Ger. Pat. 27,274, 1883), believes that aniline can only be partially recovered by the distillation of waste liquors. He therefore converts the aniline contained therein into valuable dye-stuffs. The neutral or alkaline liquors are treated with bleaching powder solution as long as a precipitate continues to form. The latter is filtered, separated from adhering lime particles by washing with dilute acid and dried. Digested with aniline and aniline chlorhydrate, a product is formed, which is soluble in alcohol with violet or bluish-black colour. For this purpose 2 parts of the precipitate, 1 part aniline oil and 1 part aniline chlorhydrate are heated in a vessel provided with a coheborator for  $\frac{1}{2}$  to 2 hours at  $175^{\circ}$  to  $180^{\circ}$  C. The product of the reaction is treated with hydrochloric acid to recover aniline, and employed either in alcoholic solution or sulphurised with 3 to 4 parts of strong sulphuric acid at  $100^{\circ}$  C. and converted into the sodium salt. In an acid dye-bath it produces nigrosine-like tints on the fibre, but with the advantage that it costs much less. The waste liquors may be also treated with chlorine, potassium permanganate, or potassium dichromate and hydrochloric acid as long as a precipitate is formed. This washed with hydrochloric acid to remove chromium compounds, etc., is either sulphurised or digested with aniline and aniline chlorhydrate, as mentioned above. The dye-stuff thus obtained is very much like the previous substance. In another process the author recommends to add to waste liquors containing aniline a dilute nitrite solution till it turns potassium iodide starch-paper blue,  $\beta$ -naphthol solution is then added, whereby  $\beta$ -naphtholazo-benzene,  $C_{10}H_7N_2C_6H_4OH$ , is formed as an orange precipitate. If  $\alpha$ -naphthol takes

the place of  $\beta$ -naphthol, a dark brown precipitate is produced on adding an acid. In both cases the yield is theoretical. The naphthols may be also replaced by phenol and naphthol monosulpho acids. The  $\beta$ -naphthol-azo-benzene can be converted into the sulpho acid and its sodium salt, which can serve as a cheap substitute for orange II, whereas the  $\alpha$ -compound prepared in the same manner cannot replace orange I, since it is chestnut-brown, assuming a violet tint with alkalis.

—S. H.

*On the Preparation of the Sulphonic Acid of Methyl-violet.* Dingl. Polyt. Jour. 254, 140.

In order to obtain the sulphonic acid of methyl-violet ("Paris violet"), an excess of sulphuric acid is added, the fluid is saturated with milk of lime, and the solution evaporated; the colouring matter, however, is partially destroyed thereby. According to a statement of the "Société Anonyme des Matières Colorantes de St. Denis," the excess of acid should be wholly or partially converted into a soluble sulphate, as of potassium, sodium, ammonium, magnesium, or zinc. Just enough water is then added to form with the dye a paste of moderate consistency. In this manner the colouring matter is obtained unaltered, and in a readily soluble form.—E. G. C.

*Nitrotoluidine M. P.  $91.5^{\circ}$  from Liquid Dinitrotoluene.* C. Ullman. Ber. 17, 1957.

BERNTSEN has shown that liquid dinitrotoluene yields by reduction two nitrotoluidines, one melts at  $77.5^{\circ}$ , and has the constitution represented in the formula,

the other melts at  $91.5^{\circ}$ , and is probably that prepared in a less pure state by Cunerth. This last body is the subject of the present communication. By elimination of the amido group, orthonitrotoluene is obtained; and by converting the amido group into the hydroxyl group, and then eliminating the nitro group, salicylol is obtained, hence the constitution  $CH_3 \cdot NO_2 \cdot NH_2 = 1 : 2 : 6$ . The hydrochloride, sulphate and acetyl and benzoyl derivatives of this base are described. By complete reduction a diamidotoluene melting at  $103.5^{\circ}$  is obtained, and having the constitution  $CH_3 \cdot NH_2 \cdot NH_2 = 1 : 2 : 6$ ; the other possible isomers have been already prepared. By the application of the diazo reaction to the nitrotoluidine, a nitro cresol  $CH_3 \cdot OH \cdot NH_2 = 1 : 2 : 6$  is obtained; it melts at  $142^{\circ}$ – $143^{\circ}$ . By reduction it yields an amido cresol  $(CH_3 \cdot OH \cdot NH_2 = 1 : 2 : 6)$ , melting about  $124^{\circ}$ – $128^{\circ}$ . By diazotising this a dihydroxytoluene is obtained, but the yield is very poor; it melts between  $63^{\circ}$  and  $66^{\circ}$ , and is probably identical with *g*-isorcinol.—H. B.

*A New General Method for the Synthesis of Aromatic Compounds.* C. Friedel and J. M. Crafts. Ann. Chem. Phys. (6), 1, 449–532.

THE paper is a monograph on the syntheses effected by the use of aluminium chloride. Most of the results obtained are already known, the following are new observations:—Amylbenzene, ethylbenzene, durene (tetramethylbenzene), pentamethylbenzene, and hexamethylbenzene, and some derivatives are described. Benzylchloride with benzene yields diphenylmethane, and with toluene, benzyltoluene, and apparently owing to admixture of the xylenes, also dimethylantracene. Chloroform and benzene yield di- and triphenylmethane, and also anthracene and phenylantracene. Carbon tetrachloride and benzene yield triphenylmethane, and some of its derivatives are easily obtained as secondary products. Acetylchloride or chloroacetylchloride, and benzene yield acetophenone or chloroacetophenone. Certain bromine derivatives of durylbenzoyl are described. Phthalylchloride and benzene yield a little anthracene and diphenylphthalide. Chloromethylacetate and benzene yield diphenylmethane. Ethylchloroacetate and benzene yield ethylbenzene. Aniline or dimethylaniline hydrochloride and methyl chloride yield dimethyltoluidine. Chloride of sulphur and benzene yield thiophenol, phenylsulphide and diphenyl disulphide.—H. B.

*The Colouring Matters of Bica Orellana.* Greshoff, N. Tijdschr. v. Pharm. Nederl., July, 1884.

Tire air-dried fruit yields 2.046 per cent bixin. Heated, it is gradually decomposed; in contact with water and air, it is gradually decolourised. It does not reduce alkaline copper solutions, even after heating with dilute sulphuric acid.—H. B.

## V.—TEXTILES: COTTON, WOOL, SILK. Etc.

*New Forms of Singing Machines for Fabrics.* Dingl. Polyt. Journ. 254, 137.

Is a machine invented by M. Jahr, of Gera, a mixture of air and gas is conducted to the burners, a pipe either conveying gas and air simultaneously, or directing a stream of air into the gas before it enters the burners. The Tulpin machine has a contrivance for the rapid removal of the singing rollers from the flames, so that the fabric can also be quickly removed.—E. G. C.

*An Improved Method of Treating Vulcanised Fibre and Like Material, to render the same Permanently Flexible.* Franklin Taylor. Eng. Pat. 10,864, August 1, 1884.

This process consists in treating the vulcanised fibre, after it comes from the cleansing bath, and while yet soft, with a solution of a deliquescent salt, such as chloride of zinc, or a mixture of glycerine or sugar water with chloride of zinc. The strength of solutions employed is from 15 to 30 Banné, according to the amount of softness required. Dry fibre may also be softened with the above solutions, but must be immersed in the bath for a longer time than the wet fibre, which requires from six to forty-eight hours, according to the thickness of the material and the flexibility required. The chlorides of tin, calcium and other deliquescent chlorides may be used instead of the chloride of zinc.—A. W.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*A New Process for Fixing Chromium.* Dingl. Polyt. Journ. 254, 132.

HITHERTO there has been found no approved method of quickly and satisfactorily fixing chromium. It is not easy to fix chromium sesquioxide or its hydrate in an insoluble form upon fabrics, by its own mordant, as the processes followed for iron and alumina will not answer. Köchlin's method of printing the material with a mixture of potassium ammonium chromate ( $K_2Cr_2O_7$  neutralised with  $NH_3$ ), sodium hyposulphite (thiosulphate), and magnesium acetate requires powerful steaming, and the fibre is easily weakened: acetate of chrome only fixes slowly and unsatisfactorily by steaming. Köchlin has, however, recently suggested a better process, according to which a solution of a salt of chromic oxide, super-saturated with alkali by simple contact with the fibre, yields up its oxide to it, no drying being necessary. The material is put in a bath consisting of 2 parts by volume of chromic acetate (16°), 2 parts of caustic soda (36°), and 1 part of water, left in for 12 hours, and finally washed thoroughly, best in running water. Almost all the chromium oxide remains fixed in an insoluble form: the more alkaline the solution, the more durable and satisfactory is the result obtained. To 5 parts by volume of the above bath, a further part of caustic soda may with advantage be added, but in this case care must be taken that the alkali does not act upon the fabric. If only 1.5 part of soda were used, instead of the 2 parts recommended, the solution would soon become muddy, and after a time gelatinise. On the same principle, oxide of iron can be fixed upon vegetable fabrics, but as  $Fe_2(OH)_3$  by itself is almost insoluble in alkalis, its precipitation must be prevented by the addition of some organic substance: the following mixture answers well:—2 parts ferric nitrate (40°), 2 parts caustic soda (36°), and 1 part glycerine (28°). Köchlin's method is very suitable for dyeing thread, etc.;

it requires little manual labour, so that, where very dark tints are desired, there is nothing in the way of a repetition of the process. Cotton, prepared as described above, is rapidly dyed on immersion in a bath of galloyanin, and it is to the latter some quercitron extract be added, methylene blue, and a little tannin, a dark blue is obtained, which withstands well the influences of soap and light.—E. G. C.

*On Alizarin Oil for Use in Print and Dye Works.* Chem. Zeit. 53, viii, 946.

SINCE the introduction of the quick dyeing process, attention has been directed to the procuring of a Turkey-red oil, which will give a clear solution with an acid reaction, and at the same time be free from any foreign substance. The alizarin oil, which is at present in use, does not satisfy the requirements of consumers, nor is the quality always to be depended upon. "Oleocarbonate" (*Ibid* viii. 65) is recommended as a substitute, as it has none of the drawbacks of the ordinary oils; can always be obtained pure, and of invariable quality; gives a clear solution with an acid reaction, and is quite as cheap.—F. T. S.

*To Test the Quality of Turkey-red Oil.* By A. Müller-Jacobs. Dingl. Polyt. Journ. 253 (11), p. 473.

THE strongly diluted solution of Turkey-red oil (mordant liquor) treated with aqueous ammonia until it has an alkaline reaction should remain clear, and show no turbidity after the lapse of some hours. The turbidity would be caused by the presence of more or less considerable quantities of solid fats, or their glycerine ethers (palmitin and stearin), and proves that either very impure castor oil, or generally other crude oils, such as rape-seed oil, sesame oil, blubber oil, cotton-seed oil, olive oil, were employed for the preparations of the red oil in question. The precipitate only appears in strongly diluted solutions, and it can be observed more distinctly with common spring water, whereby insoluble lime salts of the fatty acids are produced. R. Benemann (*Beitrag zur Untersuchung der Fette; Repertorium f. anal. Chem.*, 1884, vol. iv, p. 165) recommends as a test for the purity of oils, the determination of the melting point of the separated fatty acids. Those contained in cotton seed oil melt at 42–43° C., in olive oil at 26–27° C., in rape-seed oil at 21–22° C., whereas the mixture of fatty acids in castor oil remains liquid below the freezing point of water. The behaviour of the substance obtained by decomposing a Turkey-red oil with dilute acids at the boiling heat, also gives an indication of the nature of the raw material used in the manufacture; and whereas a good Turkey-red oil yields a substance readily soluble in dilute alcohol, the corresponding product of other crude oils is only little soluble in the same agent, gradually developing oily drops.—S. H.

*Dyeing Vegetable and Animal Substances.* Wm. Robert Lake, Southampton Buildings, London. A Communication to him from abroad by Edouard Crebassa, Chemist, and Baron Pierre Calmet Rogniat, both of Paris, France. Eng. Pat. 5670, December 7, 1883.

THIS invention has for its primary object to dispense with the heat used preliminarily in the course of the dyeing operation, "this result being obtained by making use of a peculiar mordant to be described." Its composition is as follows:—

Water .....	100 parts.
Carbonate of soda....	5 parts.
Hypochlorite of lime ..	1.5 part.

After preliminary solution, dioxide of barium. . . . . 0.1 part.

This mixture is diluted according to requirements. The bath is boiled and allowed to settle for a quarter of an hour, the clear liquid decanted into another vessel and mixed with ten centilitres of glycerine in order to precipitate the acid matters left in the decanted liquid. After cooling, the mordant may be immediately employed for dyeing purposes. "The advantages of this process are the following:—The suppression of the use of heat

applied by steam or otherwise; a saving of time in dyeing, the series of operations not lasting more than one hour, the better fixing of the colour, hot or cold washing having no effect upon articles dyed by this process. The said articles also resist the action of light, and are unaffected by the temperature of the atmosphere."

—H. A. R.

*Manufacture of Lactic Acid and the Lactates, etc.*

A. G. BROOKES, London. Communicated by T. S. Nowell, Boston, U.S.A. Eng. Pat. 5780, December 18, 1883.

THE object of this invention is twofold: (1) the production of lactic acid; (2) the production of a mordant, the essential feature of which is the presence of lactic acid. The process for the production of the lactates is as follows:—Any starch-producing vegetable substance—e.g., maize, rice or grain—in the form of meal, is mixed with warm water, at 40 to 45 °C. To this a liquid, containing a lactic ferment, is added; and in order to neutralise the acid as fast as it is formed, carbonate of lime is added. The proportions may be 100lb. of maize meal, 300lb. of water, 40lb. of the liquid ferment, and 50lb. of carbonate of lime. The resulting product, after fermentation, is neutral calcium lactate. The lactate crystals are digested with hot water, filtered, and sulphuric acid is added, sulphate of lime being formed, and acid calcium lactate liberated. After filtration the solution is concentrated and set in a cold chamber, never above 7.5 °C.; the solid crystals are pressed to remove the mother liquor, and are then ready for use. A variety of other substances, such as dextrin, inulin, gum arabic, may be fermented by the aid of soluble nitrogenous matter, and a like result secured. It is necessary, during fermentation, to avoid agitation, otherwise the lactate will be decomposed with the production of butyric acid. The second part of the invention is carried into effect by mixing four parts of the lactic acid with one part of oxalic acid. This mordant is chiefly useful in dyeing animal fibres, etc., the violent action of the oxalic acid being checked by the lactate, at the same time securing the rapid opening of the pores, and an increased bloom and softness of the dyed material, together with a superior fastness to soap, and at a lower cost than the tartaric acid mordant commonly in use. The patentee claims (1) the method of forming the lactic acid by fermentation of amylaceous vegetable substances, with water charged with a neutralising agent; (2) the treatment of the neutral crystals thus obtained as

VII.—ACIDS, ALKALIS, AND SALTS.

*Production of Sulphuric Anhydride from Nitrosulphonic Acid.* Dingl. Polyt. Journ. 254, 139.

O. V. GRUBER prepares sulphuric anhydride, not from sulphuric acid, but from the so-called chamber-crystals. To obtain these, he introduces a series of small chambers between the chamber-system and the Glover's tower. These contain, after a while, the gases in the requisite proportions for the formation of the compound

The crystals are freed from nitric acid, and nitrogen compounds generally, by heating in acid-proof retorts, through which dry air, or a mixture of oxygen and sulphurous acid, is passed.—E. G. C.

*Tungstic Acid and its Compounds.* A. K. Huntington. Eng. Pat. 222, January 1, 1884.

AN alkaline tungstate is formed by fusing the naturally occurring tungstates (e.g., wolfram and scheelite) with carbonated or caustic alkalis, with or without the addition of a siliceous or other flux. The alkaline tungstate being of great specific gravity, sinks to the bottom, and may be tapped off; or, after partial cooling, the slag may be removed, leaving the tungstate. Should the tungstate contain impurities, it may be refined by fusing it again, with addition of some substance such as silicate of soda or glass, that will take up the impurities and form a slag that can be separated, as above described, from the tungstate. The tungstate thus obtained is available for use, or it may be dissolved in water and crystallised, or treated for the production of oxide of tungsten and metallic tungsten.—F. L. T.

*Improved Baking Powder.* Andrew McDonald, Langside, Renfrewshire. Eng. Pat. 306, January 2, 1884.

BISULPHATE of potash or bisulphate of soda is substituted for the tartaric acid or cream of tartar generally used in the composition of baking powders. As an example the inventor gives the following mixture:—Rice flour, farina, or other flour, 1 to 2oz.; bicarbonate of potash or soda, 1oz.; bisulphate of potash or soda, 1 to 1½oz.—J. M. H. M.

*Improved Furnace for Recovering Soda-Ash.* G. Hitchen. Eng. Pat. 1308, January 12, 1884.

THIS process is to recover soda-ash from esparto or other liquor. Fig. 1 is a sectional elevation, Fig. 2 a sectional

FIG. 1.

FIG. 2.

described, and the production of the acid crystals; (3) a mordant composed of four parts of lactic and one part of oxalic acid.—C. C. H.

plan, and Fig. 3 a cross section on the line A B of Fig. 1. A is the fire-place situated at or near the middle of the furnace; on each side of the fire-place are one or more

calcining or burning off chambers B1. C is the flue from the left-hand chambers, D the flue from the right-hand. The gases from the flue C may pass under the furnace so as to enter the flue D, as indicated by the arrows; or the gases from the two flues may be carried away separately. E is the door between the chamber or chambers at the right-hand side of the furnace and the flue D; the cor-

FIG. 3.

responding door on the left is not shown. The liquor, evaporated to the consistency of a syrup, is run to the two sides of the furnace alternately, the doors communicating between the chambers at the two sides, and the flues being alternately opened and closed, so that the process of calcination takes place in the chambers at each side alternately, and is therefore practically continuous. —F. L. T.

*Decarbonating Carbonate of Strontia.* J. Murray, Middlesex. Communicated by Hippolyte Leplay, Paris. Eng. Pat. 1998, January 25, 1884.

AN improvement on a previous process. Moist carbonate of strontia or baryta, moulded preferably into the form of tubes, is charged into retorts, and heated in an atmosphere of steam. Anhydrous strontia is thus produced in a condition to be removed from the retorts by raking out. —G. H. Bkt.

*Manufacture of Hydrochloric Acid and Sodium Carbonate.* E. Carey, H. Gaskell, and F. Hurter, Widnes. Eng. Pat. 2117, January 25, 1884.

SODIUM chloride and hydrogen sodium sulphate are heated together to redness, hydrochloric acid being evolved, and neutral sodium sulphate produced. This neutral sodium sulphate is dissolved in water, and certain impurities are removed from the solution, into which ammonia and carbonic acid gases are then passed, sodium bicarbonate becoming precipitated, and the solution then contains ammonium sulphate, sodium sulphate, and ammonium bicarbonate. Or instead of the gases, ammonium bicarbonate may be prepared separately, and then added to the sodium sulphate solution. The sodium bicarbonate is separated by filtration, and calcined. The solution is heated in stills to drive off the volatile ammonia compounds, and evaporated further to dryness, leaving a mixture of sodium and ammonium sulphates, which, on being heated in an atmosphere of steam, becomes converted into free ammonia and hydrogen sodium sulphate, ready for use over again. —G. H. Bkt.

*Ammonium Chloride.* T. Heskin. Eng. Pat. 2491, January 31, 1884.

To obtain ammonium chloride: Sodium borate is decomposed by sulphuretted hydrogen under pressure, the precipitated boric acid is dissolved in strong ammonium hydrate, forming ammonium borate, which then appears to undergo double decomposition with common salt, producing ammonium chloride and sodium borate. —F. L. T.

*Improvements in the Treatment of Certain Residual Salts formed in the Manufacture of Caustic Alkalis.* Jno. Healey, Liverpool, Geo. Pryde, Liverpool, and W. H. Swim, Runcorn. Eng. Pat. 2796, February 6, 1884.

The crude salts eliminated from caustic alkali solution by fishing during concentration are, preferably when in

solution, oxidised by the addition of nitre or the blowing in of air, etc., and then dried and fused. The iron, as also a large proportion of the silica and alumina, sinks to the bottom of the fusing vessel, and the clear, hot liquid above is drawn off, allowed to cool and broken into pieces for use as required. —A. R. D.

*Manufacture of Bichromate of Soda.* By Thomas Carlile and James Park, Millburn Chemical Works, Glasgow. Eng. Pat. 3392, February 16, 1884.

THE object is to obtain non-deliquescent anhydrous crystals. A solution, obtained in any way, is concentrated until the hydrated salt melts in its water of crystallisation, and is then introduced into a steam-jacketed vessel, provided with a mechanical stirrer. The vessel is heated by steam to a temperature not exceeding 200° C., and the solution is agitated by means of the stirrer until all the water has been expelled, and the salt has separated in a mass of anhydrous granular crystals. —J. M. H. M.

*An Improved Process for Extracting Sulphur from Sulphide of Hydrogen.* G. F. Reiborn, London. Communicated by Dr. H. von Miller and Carl Ope, of Hirschau, Austrian-Silesia. Eng. Pat. 10,743, July 29, 1884.

SULPHURETTED hydrogen is passed through a retort or series of tubes filled with fragments of gypsum and kept at a red heat. The outlet communicates with a suitable condenser for the liquid sulphur, which separates according to the following equation:

The residual calcium sulphide may be reconverted into sulphate by blowing air through the retorts. The caloric generated by this operation is utilised to heat another retort in which the decomposition of sulphuretted hydrogen is going on. —A. R. D.

*Improvements in the Manufacture of Potassium Carbonate and Bicarbonate.* Fannie Brown, London, relict of W. Cowell Brown, deceased. Eng. Pat. 11,007, August 6, 1884.

POTASSIUM nitrate is mixed with carbonaceous material such as coal-dust, and subjected to pressure to diminish the bulk and lessen the rapidity of combustion. This mass is burned in suitable vessels, and the ash washed, clarified, and crystallised, or treated in solution with carbonic acid for the production of bicarbonate. The carbonic acid is derived from the combustion of the nitre and coal-dust. —A. R. D.

*Improvements in the Manufacture of Carbonate of Soda.* Fannie Brown, London. Eng. Pat. 11,008, August 6, 1884.

NITRATE of soda and coal dust are burnt as in the preceding patent (11,007), and the ash washed. The solution is concentrated for crystallising, or evaporated to dryness by the combustion of the carbon monoxide generated in the first operation. —A. R. D.

*Improvements in the Manufacture of Bicarbonate of Soda.* Fannie Brown, London. Eng. Pat. 11,009, August 6, 1884.

THE carbon monoxide produced in the manufacture of carbonate of soda by the combustion of nitrate of soda and coal-dust is used as fuel to evaporate the soda solution to proper strength, and the carbon dioxide resulting from its combustion is utilised for the conversion of the carbonate of soda into bicarbonate. —A. R. D.

*A New and Improved Process of Dissolving the Lime out of Phosphates or other Calcareous Minerals to form a Caustic Solution capable of replacing Soda in certain operations, with consequent Enrichment of the Residual Substance.* Michael Cahen, Brussels. Eng. Pat. 11,336, August 16, 1884.

PHOSPHATIC limestone is calcined to drive off the carbonic acid, and then moistened to slake the lime

contained. The mass is then boiled with calcium chloride solution which dissolves out the lime, leaving a residue of almost pure calcium phosphate. The solution of lime thus obtained is, on account of its valuable detergent properties, capable of replacing soda in many industries. At least two parts of calcium chloride and six parts of water are required to dissolve three parts of lime.—A. R. P.

#### Improved Apparatus for Making Salts of Ammonia.

W. Arrol and J. Meikle, jun. Eng. Pat. 12,174, September 9, 1884.

This apparatus is for the production of ammonium salts from the ammonia distilled from gas liquor, etc., by combining it with acid. Fig. 1 is a plan, Figs. 2 and 3

fitted with a pulley (17). A movable cover (24) is provided for covering the open part of the vessel, excepting when the tray is being moved in or out. A pipe (25) is connected to the dome to carry away sulphuretted hydrogen, etc.—F. L. T.

#### Production of Carbonate of Ammonia. William Edward Gedge. A Communication from Frederick Carl Glaser. Eng. Pat. 5761, December 17, 1884.

The process consists in heating salts of ammonia with equivalent quantities of alkaline carbonates, to which a small quantity of bicarbonate has been added. The reaction takes place in a very perfect manner, and the product is exceedingly pure.—E. J. B.

vertical sections as at right angles to each other. The ammonia combines with the acid in a copper vessel (4), rectangular in plan, one half being permanently covered by a curved dome (5), which, in transverse section as seen in Fig. 3, is a continuation of one outer side of the vessel, whilst it is at its inner part continued downwards in a partition or curtain (6) dipping down a little below the surface of the acid, the dome and curtain thus enclosing a space above one part of the acid. The bottom (7) of the vessel is made with a deeper part or recess (8), which latter is at the part not covered by the dome (5); and in this recess (8) there is placed a copper dish or tray (9) to receive the crystallised salt of ammonia. The acid is supplied by a pipe (10) as required, and the gaseous ammonia is conveyed from the still by a pipe (11) connected to a horizontal pipe (12) placed on the higher part of the bottom (7) and close to the vessel's side furthest from the recess. The horizontal pipe (12) has perforations made in it on the side facing towards the middle of the vessel, and the jets of vapour issuing from them produce currents in the liquid which carry the crystals as they are formed into the tray (9). When a quantity of crystals has accumulated in the tray, it is lifted out of the vessel (4) and the crystals are emptied from it into a receiver (13), a framing (14) being constructed over the vessel and having fixed on it a pair of rails (15) on which runs a small wheeled truck (16)

#### VIII.—GLASS, POTTERY, AND EARTHENWARE.

##### The Manufacture of Improved Plastic Compounds. M. Mackay, Camberwell. Eng. Pat. 5467, November 20, 1883.

This invention relates to the manufacture of compositions suitable for moulding into such articles as screw stoppers for bottles, jars, casks, and similar vessels; for brushes, the bristles of which are secured in plastic materials; for buttons, and for various other articles required to stand a high degree of heat, whether dry, moist, or liquid. For screw stoppers and other articles requiring to be free from taste and smell the following ingredients are employed in about the proportions given:—

75	pounds of lac (preferably shellac).
28	" " gum sandrac.
28	" " rosin.
28	" " ivory black, or other fine carbon.
168	" " asbestos, or silicates.

The resins being melted in a suitable vessel, the carbon is added and thoroughly incorporated with the liquid mass, after which the "asbestos or other fibrous matters or silicates" are put in the vessel. The whole is well stirred until it forms a stiff paste, which can be moulded in dies or rolled into sheets. Other ingredients, when

heated, can be mixed and worked into a paste by being passed through hot rollers. This composition is not affected by either dry or moist heat at 200° F., nor by hot water at 210° F. When it is immaterial that the composition should be free from taste and smell, gum kauri can be substituted for the gum sandrac, and asphaltum for the carbon.—E. G. C.

*Improvements in Continuous and Semi-continuous Kilns for Burning Bricks, Pottery, etc.* H. Knowles, Woodville, Leicester. Eng. Pat. 351, January 2, 1884.

THE object of this invention is to secure increased facility of control in the working of the kiln and in the transmission of heat from one chamber to another, and also the economy of the heat produced. A series of kilns is constructed in a line separated from each other by partition walls. The kilns are of the down-draught type, and are provided with fireholes and shield walls; the outlet flue from each chamber is in communication with a connecting flue having branches to the main channel leading to the chimney, and also in communication with the adjoining chamber by a flue in the interior of the partition wall, emerging into the chamber by perforations; both of these flues are controlled by dampers. Each chamber communicates with the adjoining one directly by an opening at its upper part closed by a damper. The first chamber of the series is lighted after being filled with the green goods, and put in communication with the chimney, until all the steam has passed away, when it is put into connection with the next of the series through the flue formed in the partition, and so on until the whole series is in operation and utilizing the heat given off by the first chamber. When the goods in the first chamber are finished, the flue through the partition is closed, and the chamber short-circuited into the next one, in which the fire has been lighted in the meantime, so as to equalise the excess of heat in the first chamber between the two; as soon as this has happened the top flue is closed, the air-holes opened, and the interior allowed to cool. The same operation is carried out with the whole of the chambers in succession, more even results being given, and that with considerable economy of fuel. The claims are—(1) the construction of kilns as described, with partition walls having flues, passages, and dampers; (2) the construction of kilns having, as described, a communication and damper at the top; (3) forming a fireplace in the opening, between the chambers claimed in (2); (4) the combination of the various flues, passages, etc., as described; (5) the general arrangement and combination of parts constituting the kiln as described.—C. C. H.

*Improvements in Ovens or Detached Kilns for Burning Bricks, Pottery, etc.* H. Knowles, Woodville, Leicester. Eng. Pat. 352, January 2, 1884.

THIS patent deals with improvements in down-draught detached ovens or kilns, and its object is the utilisation of the waste heat of any furnace of a series of such furnaces, when used for burning bricks, pottery, etc. A series of furnaces is built preferably in a line; it has one common connecting flue, which between each furnace is in connection with a common main flue leading to the chimney. Dampers are to be placed between each furnace so that they may be thrown into circuit through the common connecting flue, or put into direct communication with the chimney. Distributing flues communicate between the connecting flues and the space formed between the walls and the interior central down-draught flue which passes out of the body of the furnace through the perforated bottom. The *modus operandi* is as follows:—The fire in the first furnace of the series is lighted and the damper in the connecting flue closed, that in the main flue to the chimney opened; when the steam from the green goods has quite ceased the heated products of combustion are sent through the next of the series until the goods in that likewise are dried, and so on until the whole series is working on the products of combustion from the furnace first lighted. The whole of the heat is thus utilised before entering the chimney.

As soon as the goods in the first furnace of the series are completed, its fire is cut off from the rest of the series, and the fire is lighted in the second of the series, and so on until the complete operation is ended in the whole of the furnaces or kilns. The patentee claims (1) providing circular ovens or kilns with the connecting and branch flues as described; (2) providing rectangular kilns with a similar arrangement of flues for the purpose described; (3) the combination of parts forming the whole series of kilns as described.—C. C. H.

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, CEMENTS.

*Chemical Changes which Accompany the Hardening of Hydraulic Cements.* H. le Chatelier. Bull. Soc. Chem. 42, 82-89.

THE setting of hydraulic cements is the effect of the crystallisation of dissolved substances; in ordinary mortars the act of drying in addition plays a part. The most important body concerned in the hardening of hydraulic cements is the compound  $\text{CaO} \cdot \text{SiO}_2 + 2.5\text{H}_2\text{O}$ —this formula has not been obtained by analysis, but by analogy with the crystallised compound  $\text{BaO} \cdot \text{SiO}_2 + 3\text{H}_2\text{O}$ —which is decomposed by water into free lime and a salt of silicic acid ( $2\text{SiO}_2 \cdot \text{CaO} + \text{Aq} \cdot ?$ ); by carbonic acid and water into silica and carbonate of lime. The first decomposition is arrested when the water contains 0.052 per mil. of lime. The formation of this silicate by hardening is produced either by combination of the two constituents or by decomposition of silicates richer in lime, or perhaps by simple hydration of the anhydrous compound. The compounds of lime with oxide of iron or alumina which can exist in water in presence of excess of lime have the formula  $\text{R}_2\text{O} \cdot 4\text{CaO} \cdot 12\text{H}_2\text{O}$  (R = Al or Fe), and are split up with water alone, but decomposition stops in presence of water containing, at 15°, 225 and '6 per mil. of lime respectively. Iron and alumina are important as fluxes in preparing the mortar by bringing the silica into combination with the lime. The absorption of carbonic acid is of no moment in the hardening of cement, calcium carbonate always forming a superficial layer. This layer is, however, important, for, as the carbonate gives up a minimum quantity of lime to water, the durability of the cement is thereby increased.—J. C.

*Improvements in the Manufacture of Cement and Apparatus therefor.* R. Stone, London. Eng. Pat. 153, January 1, 1884.

THE improvement in the process of manufacture consists essentially in grinding the materials in a red-hot state, giving a better prepared material with less consumption of power. The burnt clinkers pass red-hot through steel crushing rolls of special construction, and thence to the grinding rollers, the bed plate of which is made concave and adapted to the lower roll, so that the crushed material after passing between the rollers is further ground between the lower roll and the bed plate. A moulding machine is described, also a machine for grinding the slurry, constructed on the principle of a pestle and mortar.—H. J.

*Improvements in the Manufacture of Cements.* F. W. Gerhard, Wolverhampton. Eng. Pat. 1504, January 16, 1884.

TO certain impure silicates of alumina and iron the patentee adds lime, and claims "to make cement from the roteh bar or bovin, and what is known as black lime in this district, in the way above described."—H. J.

*Improvements in the Manufacture of Portland Cement.* E. W. Harding, Bishopwearmouth. Eng. Pat. 1707, January 18, 1884.

THE patentee claims the application of gaseous fuel, in kilns of special construction, to the burning of Portland cement, together with the utilisation of the waste heat,

for the carbonisation of coal and the heating of the drying floors. Also the mixing of a certain proportion of resin with the cement mixtures to assist the calcination.—H. J.

*Improvements in the Manufacture of Portland Cement.*  
R. W. Lesley and J. M. Wilcox, of Philadelphia, Pa.  
Eng. Pat. 1884, January 22, 1884.

THIS invention has for its object to enable cement powder to be moulded into forms or shapes suitable for the kilns, as respects size, adaptability to free draught, and the like, while dispensing nearly, if not altogether, with the water ordinarily required to bring it to the pasty condition for this purpose. The object in view is attained by compressing the powdered materials, merely damped with water, but not in a pasty condition, by heavy pressure between rollers having cells or cavities wherein the powder is moulded into blocks of the requisite size. Several modifications of the process are described, in one of which about four per cent. of any liquid combustible are added to the damped materials.—H. J.

*Improvements in the Manufacture of Artificial Stone, Facing Slabs and Blocks.* J. Elliott and F. J. Parsons, Hastings. Eng. Pat. 3363, February 15, 1884.

THE object in this invention is to provide artificial stone blocks with hard adamantine wearing surfaces. The body of the stone is composed of a mixture of sea-shore boulders, Bath, Portland and York stone well crushed and mixed and saturated with water; with three parts of this mixture one part of Portland cement is mixed. The blocks are cast in suitable moulds, in which space is left for the addition of the hard facing surface, which is made by mixing finely crushed and sifted Kentish rag and Bath stones with an equal part of cement. The face of this coating is again made harder by the addition of an eighth of an inch of a mixture of two parts of cement with one part of moistened fine sifted Kentish rag and Bath stones. The blocks thus formed are soaked in water and exposed to the action of the air to harden. The surfaces thus produced are harder and less slippery than natural or artificial stones otherwise prepared. The claim is made for the general method of manufacture, as above described.—C. C. H.

*Improvements in the Manufacture of Portland Cement.*  
J. W. Matteson, W. J. Chapman, and T. G. Matteson.  
Eng. Pat. 13,237, October 6, 1884.

THIS invention has for its object the improvement of the quality of the mixture of chalk, clay and water in cement making, technically known as "slurry," and the obtaining at a particular stage of the manufacture of a more complete admixture and homogeneity of the materials, with perfect disintegration, and free from small particles of chalk, hitherto met with in all all known processes of manufacture. The apparatus consists of a rotary sieve or "tempe," preferably of conical shape, revolving in a well provided with an exit pipe at one end. Around the exit a fixed flange is built into the masonry, and an iron disc at the end of the sieve revolves in contact with it. The slurry which has passed through the meshes of the sieve is further mixed and ground between the discs at the exit. To clean the meshes of the sieve a cam wheel is fixed upon the same, which causes a hammer to strike it repeatedly at each revolution of the machine, thereby shaking the obstructions out of the meshes.—H. J.

## X.—METALLURGY, MINING, ETC.

*On Japanese Bronzes.* Dingl' Polyt. Journ. 254, 138.

IN the Bavarian Museum of Industry at Nuremberg are eighteen Japanese bronze plates, remarkable for the excellence of their workmanship. According to G.

Marquard, these plates consist of five distinct alloys, the composition of which is as follows:—

	Copper	Tin	Lead	Zinc	Iron	Arsenic
No. 1. Brass	73.28	—	0.79	25.71	—	—
No. 2. O	72.60	1.0	11.71	11.18	0.21	—
No. 3. O O	75.13	3.18	15.67	5.61	0.15	—
No. 4. C	82.17	3.96	13.31	0.28	0.21	—

No. 5. Copper (containing traces of Lead and Iron).

It will be seen that these alloys range from brass to pure copper.—E. G. C.

*A New or Improved Process for the Treatment of Sulphurous and Arsenical Compound Ores containing Nickel, Cobalt, and other Metals.* Benjamin J. B. Mills, Southampton Buildings, Middlesex. Communication from Pierre Mauhé, Lyons, France. Eng. Pat. 3355, November 13, 1883.

THE ore mixed with suitable fluxes is fused in a cupola, or reverberatory furnace, to separate from gangue, and is then transferred to a converter, where it is submitted to the action of air, the "blow" being continued until 1 or 2 per cent. of iron and about 15 per cent. of metalloids remain. Further action would cause oxidation of nickel and cobalt. This matte, containing little else than nickel, cobalt, copper, sulphur, arsenic, and the above-stated quantity of iron, may be refined either by attacking with hydrochloric acid, and separation by any known wet method, by electrolysis, or by a second dry-refining process. The last-named process may be used to produce an alloy of the metals contained in the matte, and consists in again blowing air through the melted mass until the iron and sulphur have been oxidised, when the resulting product is reduced with carbon and lime, by which means the sulphur is completely eliminated. If the matte contain only nickel, sulphur, iron, and metals more oxidisable than iron, pure nickel will result from this treatment; otherwise the product may be granulated in water, and afterwards electroalised. A small quantity of nickel and cobalt pass into the slag during the lime-carbon reduction.—W. G. M.

*An Improved Pot for Melting Metals.* By John Harsant. Eng. Pat. 109, January 1, 1884.

THE improvement consists in placing a deflector ring of semi-circular section over the edge of the melting pot and a little distance above the edge, so that the flame and heated air passing up the sides of the pot are bent over the edge, and thrown downwards in the interior so as to play on the surface of the metal or other substances which are to be heated.—J. T.

*Improvements in Gold Amalgamating.* By B. C. Molloy, London. Eng. Pat. 143, January 1, 1884.

THE object of the invention is to prevent the sickening of the mercury employed in amalgamating gold and other metals, and to increase the contact between the mercury and the metals to be amalgamated. A typical arrangement of apparatus consists of a shallow box with porous bottom carrying a half-inch layer of mercury. A continuous band of linen or other material carried by two drums just dips into the mercury surface and is moved over that surface by the rotation of the drums. Beneath the porous bottom is a trough fitted with carbon, platinum, lead or other suitable anode, and containing a sufficient quantity of an aqueous electrolyte in contact with the porous bottom carrying the mercury. On connecting the apparatus with any suitable source of electricity giving an electromotive force of about four volts, and making the mercury layer the cathode, the hydrogen evolved, when a suitable electrolyte is employed, prevents the "sickening" of the mercury. The slimes to be treated are passed down an inclined shoot into the surface of the mercury, and by the motion of the endless band are carried closely in contact with the "quick"

mercury across the box. When dilute sulphuric acid is employed as electrolyte, the anode may be of lead; but when an alkaline electrolyte is used, an anode of carbon platinum is preferred.—J. T.

*Treatment of Scrap Zinc.* By A. K. Huntington and J. Humphrys, London. Eng. Pat. 224, Jan. 1, 1884.

The scrap zinc is assorted and cut into small pieces, all iron, and pieces containing solder upon them being removed. After washing in hot water, which may contain a little alkali, the zinc is melted and cast into ingots. The pieces containing solder are also washed, melted, and allowed to cool slowly, the metals being separated as the mass cools. This melting and cooling can be repeated several times if necessary. The portion containing mostly solder may be melted again and the zinc separated from it by exposure to air or by poling with superheated steam. The portion containing mostly zinc may be treated as above described by repeatedly melting and slowly cooling. The dross produced in melting the zinc is treated by distillation, but the quantity of dross may be much reduced by introducing the pieces to be melted at a low level in the melting pot, passing them down a tube.—J. T.

*Improvements in Blast and Cupola Furnaces.* By J. Swain, Oldham. Eng. Pat. 914, January 8, 1884.

THE invention consists in making between the walls of the furnace a chamber extending from below or about the level of the tuyers to the upper part of the cupola; the gases in a highly heated state are forced through this chamber from the lower to the upper part of the cupola, and heat is thus imparted to the tuyers (which are laid in the chamber), and so the air for combustion which is forced into the furnace through the tuyers. In this chamber is sometimes placed chlorine or sodium chloride; the blast for the furnace forces the gases through the lower passages from the furnace into the chamber over the sodium chloride, from which fumes are raised, and these fumes with the other gases go from the chamber through the upper passages into the furnace at or about the point of fusion, and thus purify the metal and accelerate the fusion.—J. T.

*Production of Yellow Metal.* By T. Parker, Wolverhampton. Eng. Pat. 1223, January 11, 1884.

THE chief object of this invention is to produce economically a yellow metal of great tensile and compressive strength and hardness. This is effected by melting copper, 50 parts; spelter dross, 25-30; spelter, 12-17; tin,  $\frac{1}{2}$ -2 parts, with a flux of the following composition added to a paste:—Salt cake, 5 parts; coal-dust, 5; silica, 15; bone ash, 20 parts. Manganese or copper sulphate, or the chlorides of these metals, and also common salt, may be used in place of the salt cake. This flux is also applicable to the founding of brass and bronze generally.—J. T.

*Improvements in Regenerative Furnaces.* By T. B. Massicks, Millom. Eng. Pat. 1261, January 11, 1884.

THE object of this invention is to improve the construction of furnaces for melting, puddling, or reheating steel, iron, etc., so as to obtain greater facilities for cleansing such furnaces, and removing the dust that accumulates in the regenerator, and also to obtain a more extended distribution of the gas and air employed in heating the furnace. These objects are effected by forming a separate connection for the admission of air to the furnace, and so preventing the air from passing through the joints of the brickwork and coming into contact with the gas as heretofore, until the moment when the air descends through the roof, when it comes into contact with the gas issuing from the regenerator, thus the greatest intensity of heat is obtained at the point where it is most needed. The gas issuing from the regenerator is conducted through a number of passages inside the furnace, and extending the whole width of it or nearly

so. Air is conducted from the regenerator through a suitable tube at the end of the furnace to an opening formed in the roof of the furnace, preferably at either end; this opening is covered with a loose top or casing with an enlarged semi-circular or suitably shaped end; this loose top may be removed at any time for cleansing purposes or repairs, without interfering with or stopping the furnace. The usual reversing arrangements and regenerators are employed, and suitable cleaning doors are fitted in the gas passages leading from the regenerator.—J. T.

*Manufacture of Phosphates.* S. Gilchrist Thomas, London. Eng. Pat. 1341, January 12, 1884.

HIGHLY phosphoric molten iron is poured on hydrated or carbonated alkali, and the whole is maintained at a high temperature in presence of air on the basic or neutral hearth of a Siemens gas furnace or a converter. Special provisions are detailed for preventing loss of alkali by volatilisation. The resulting slag consists essentially of alkaline phosphate suitable for use as a manure or for the preparation of the crystallised salt.—G. H. B.

*Manufacture of Alkalies, Phosphates, etc.* S. Gilchrist Thomas, London. Eng. Pat. 1342, January 12, 1884.

THE foregoing process is extended by the use of common salt instead of alkali, and the reaction is facilitated by admitting superheated steam with the air blast. The production of chlorine, hydrochloric acid and sodium phosphate is thus effected, and these substances are recovered in a suitable way.—G. H. B.

*Manufacture of Alkaline Silicates.* S. Gilchrist Thomas, London. Eng. Pat. 1343, January 12, 1884.

AN extension of the two preceding processes in which highly siliceous pig iron is caused to act on alkaline chlorides at a high temperature in presence of air and steam for the production of chlorine, hydrochloric acid and alkaline silicate.—G. H. B.

*An Improved Method or Process of Extracting Aluminium from Substances containing the same.* William Robert Lake, Southampton Buildings, London. Communication from Fredk. J. Seymour, Wolcottville, Connecticut, and Wm. Hy. Brown, New York, U.S. Eng. Pat. 1639, January 17, 1884.

THE aluminous ore (kaolin has yielded the best results) after drying and crushing, is mixed with an ore of zinc—preferably calamine—which has been roasted to remove sulphur and pulverised, together with carbonaceous matter and suitable fluxes. The proportions recommended are: Kaolin, 60 parts; zinc ore, 60 parts; carbonaceous matter—e.g., a mixture of equal parts bituminous coal and willow charcoal—120 parts; and common salt, 3 parts. This mixture is introduced into cylindrical retorts, of fire-clay or of cast-iron lined with clay, which are then closed by conical stoppers, each of which is provided with a very small aperture at the apex. These retorts are arranged in a suitable furnace chamber, heated by a coal fire. The reduction of the aluminium is facilitated by the presence of the zinc with which it forms an alloy. When the metal flows freely the stoppers are removed, and the alloy is tapped. The alloy is to be used as such, or to be separated by distillation, or by gravity (aided by a "jiggling" motion), the heavier zinc sinking to the bottom.—W. G. M.

*Treating Ores or Scoria containing Copper or Nickel.* By J. H. Johnson, London. Communicated from E. Hermite, Ronen. Eng. Pat. 2157, January 25, 1884.

THE ores or scoria, containing copper or nickel, are reduced to a fine powder and placed in a rotating vessel. A solution of ammonia is introduced into the vessel, the

amount of ammonia being regulated according to the richness in metal of the ore or scoria, and the air is then compressed to a pressure of from about three to four atmospheres. The vessel is then rotated for from about thirty to sixty minutes according to the nature of the ore. After settling, the liquid is decanted; the ore is washed again with a fresh supply of liquid if required, and finally with water, but always under pressure. The liquid obtained above, is subjected to electrolysis in iron vessels containing cathodes of cast-iron and anodes of carbon. A small quantity of caustic soda or potash may be added to the liquid to render it a better conductor. The copper or nickel deposited is afterwards run into ingots.—J. T.

*Malleable Ferro-Nickel and Ferro-Cobalt and their Alloys.* A. M. Clark, London. Communicated by the Société Anonyme dite Fonderie de Nickel et Metaux Blancs, Paris. Eng. Pat. 2573, February 1, 1884.

This invention relates to the manufacture of malleable ferro-nickel and ferro-cobalt, by the direct employment of pigs or mattes of these metals (without that part of the subsequent refining which would have for object the elimination of the iron), which are combined at one and the same fusion with ferro-cyanide, or potassium cyanide, and one of the oxides of manganese (manganese, for example), adding, at the moment of running, a small quantity of aluminium. The pigs to be utilised are obtained by the simultaneous fusion of ores of nickel and cobalt, nickel and chromium (chrome iron ore), cobalt and chromium, or of nickel cobalt and chromium, using pure ores of nickel or cobalt with the addition of ores of chromium when the products are to contain a small percentage of nickel or cobalt and a large percentage of iron; all these pigs or mattes, whether simple or mixed, containing a low percentage of sulphur, are what it is intended to utilise, with or without an addition of soft or crude iron. These alloys, fused with the cyanide as above, are rendered permanently malleable even after a second fusion, and are adapted for casting, rolling, drawing, wire-drawing, and hammering. Whilst soft iron loses, by a second fusion, its fibrous texture and becomes crystalline and brittle, this same soft iron preserves its malleability after the second fusion, if it had been previously mixed with a certain quantity of the malleable products above described.—J. T.

*Separation of Lead from Precious Metals.* By E. H. Russell, Park City, U.S.A. Eng. Pat. 5430, March 25, 1884.

In the ordinary process of leaching metals from ores by chemical solutions, the compounds of silver and gold are extracted by being dissolved out with a solution of hyposulphite of an alkali or alkaline earth. The sulphate and chloride of lead, however, are often present in the ores, and are likewise soluble in the hyposulphite solution. This dissolved lead contaminates the bullion produced, and necessitates expensive refining operations. The author finds that the addition of a soluble carbonate to the hyposulphite precipitates the lead alone and leaves the silver, gold and copper that are present in the solution unprecipitated. The process is intended to be used particularly upon ores or products which have been previously subjected to a chloridising roasting, but it is also applicable to some raw ores in which the precious metals exist in forms soluble in hyposulphite solution.—J. T.

*Improvements in Processes and Apparatus for Converting Iron or Making Steel.* Thomas Williamson, Wishaw, Lanarkshire. Eng. Pat. 6082, April 8, 1884.

This invention consists in a combination of the Bessemer and Siemens processes. The converter is of somewhat different shape to that now in use, the tuyeres delivering the gas not in the direction of the main vertical axis of the vessel as usual, but tangentially to circles having their centres in the trunnion axis; the mouth of the converter is diagonally opposite to the tuyeres, and is

closed with a luted cover during the blow. The gases, on account of the position of the tuyeres, pass spirally round the trunnion axis, thus depositing much of the iron and slag carried with them, and thence through the trunnions themselves, which are hollow and of considerable diameter, to regenerative chambers. The trunnions rest on roller-bearings, and are connected with the regenerators by a water-cooled joint. The air is conveyed from the blowing engine by a fixed main, and thence through jointed tubes to the tuyere-box. In use, the converter is turned down, by worm-wheel or spur-wheel teeth on one of the trunnions gearing with a worm or pinion beneath, and charged in the usual way; the cover is then luted on, the vessel turned up, and the blow started and continued for ten or fifteen minutes; it is then lowered and the blast shut off, and air and gas are passed through the regenerators, the remaining operations being carried on and completed as in a Siemens furnace. The cover is removed from the converter-mouth, which then serves the purpose of a working-door. The metal is tapped by turning the converter down, as in the Bessemer process, the slag being afterwards removed by inverting the vessel. Acid or basic lining may be employed, but the patentee prefers the former.—W. G. M.

*Amalgamating Apparatus.* By A. Miller, London. Eng. Pat. 9151, June 18, 1884.

A U-SHAPED vessel is provided, the one limb being preferably larger in sectional area than the other. This vessel is charged with mercury when the amalgamation is to be carried on in the cold, or with molten lead or other suitable metal, when the operation is to be carried on at a high temperature, and in that case the apparatus is placed over a fire or in a tin to keep its contents hot. Near the mouth of the smaller limb is placed a lateral feed aperture, surmounted by a hopper containing the ore or tailings to be treated. The material can be carried into the vessel from the hopper either by a screw or a plunger. The charge is thus pushed into the limb and is caused to descend, rising again through the mercury or molten metal in the larger limb. Both limbs are closed at the top and have mounted centrally within them vertical shafts, carrying several sets of inclined blades. In the smaller limb there are several grids, and at the bottom of the larger one is also fixed a grid. In the latter limb there are several fixed blades to keep the contents from rotating. At the top of the wide limb there is a lateral opening for discharge of the spent material. Also at the bottom bend there is a passage for drawing off the amalgam.—J. T.

*An Improved Manufacture of Sheet Metal from Lead, Tin and other similar Metals or alloys thereof, and Apparatus used for that purpose.* Chas. Denton Abel, Southampton Buildings, London. Communicated by Reinhard Poensgen, Dusseldorf. Eng. Pat. 9910, July 8, 1884.

This is a method for "squirting" metal plates. The melted metal is run into a cylindrical chamber with an accurately-fitting vertically-sliding floor actuated by a series of hydraulic rams; on raising the floor, the metal is forced between two sets of movable cheeks, the distances between which may be accurately regulated by means of hand-wheels and screws, according to the width and thickness of plate required. These cheeks or dies are situated at the top of the chamber, and allow the solidified metal to pass out in an uninterrupted sheet of the precise dimensions desired.—W. G. M.

*Improved Refractory Substance.* J. H. Johnson, London. Communicated from abroad by Messrs. J. B. Mallion and Son, Turin. Eng. Pat. 9917, July 8, 1884.

This invention consists in the preparation of crucibles, retorts, etc., of magnesia. Magnesia free from foreign matters is employed, which may be obtained by roasting

magnesite, gisbertite, periclase, or other minerals or compounds of magnesia, but it is preferred to employ magnesia obtained from sea-water in order to obtain a product chemically free from silica. A suitable quantity of this material, made into cakes, is masted at an intense temperature, and the product thus obtained is coarsely ground. Another quantity of the magnesia is maintained in a caustic condition, and the two products thus obtained are mixed together according to the purpose to which they are to be applied in the proportion of from about 60 to 90 per cent. of the roasted magnesia, and from about 10 to 40 per cent. of the caustic magnesia. The proportion is, however, varied according to the purpose to which the product is to be applied. This mixture is moistened with water containing starch, flour, potassium carbonate, or other binding material, and is well rammed into moulds. The objects thus obtained, after being dried, are ready for use, but in some cases it is desirable to expose them to a high temperature, preferably not less than that of a Siemens-Martin gas furnace.—J. T.

*Improvement in Tuyeres used in the Manufacture of Iron and Steel.* Christopher Thompson, Sunderland, Durham. Eng. Pat. 10,292, July 18, 1884.

THE improvement consists in piercing the tuyeres of converters or furnaces with thin broad passages, tapering slightly towards the outlet, instead of with the circular channels usually employed. The advantages claimed are: That fewer tuyeres are necessary for passing a given quantity of gas, and hence a saving in their consumption; that there is less friction between the air and the walls of the passages, so that less blast-pressure is needed; that as the tuyere wears away to the enlarged part, more air will pass, and will thus give warning of the fact; that some of the difficulties connected with fixed converters are removed, and that in moveable converters, horizontal blowing may be successfully employed, which will prevent metal from being blown out of the mouth; and, moreover, the scouring action of the molten metal will take place on the more refractory converter-bottom, instead of on the plug and tuyeres, and greater uniformity of pressure will also result; that a greater charge than heretofore may be worked off in any given converter, and the blast-box and tuyeres are smaller and lighter, and the plug and tuyeres less acted upon, whilst repairs are more readily effected.—W. G. M.

*Improvement in Tuyeres used in the Manufacture of Iron and Steel.* Christopher Thompson, Sunderland, Durham. Eng. Pat. 10,574, July 25, 1884.

IN order to lessen the friction of the air passing through the converter tuyeres, and to cause due notice of their wearing away, and of the consequent dangerous approach of the molten charge to the tuyere plate, by the increased volume of air passing, the patentee enlarges the circular perforations at the inlet end to a depth of from 5 to 7 inches. The tuyeres may be made in the moulds commonly used, the piercing rods alone being different.—W. G. M.

*Treatment of Ores containing Antimony Sulphide.* By J. Simpson and E. W. Parnell, Liverpool. Eng. Pat. 11,827, September 1, 1884.

PULVERISE the ore to pass through a forty-mesh sieve and add it to an aqueous solution, preferably hot, of a fixed alkali, of a fixed alkaline sulphide, or of a sulphide of the metal of an alkaline earth. The decanted solution is treated with just sufficient hydrochloric acid or other cheap acid to precipitate the antimony sulphide. Instead of acid being employed, air may be passed into the solution, or the solution may be evaporated to dryness and the resulting compound further treated. The authors find that ore of the fineness indicated above readily dissolves in sodium sulphide solution of about 40° Tw. or in calcium sulphide of about 10° Tw.—J. T.

## XI.—FATS, OILS, AND SOAP MANUFACTURE.

*Treatment of Mineral Oils in Combination with other Matters, and Producing therefrom Soap, Candles, and other Articles.* W. Green, St. Lawrence. Eng. Pat. 5954, December 31, 1883.

THE inventor refers to letters patent previously granted to him, and dated June 18, 1881 (2682), and September 5, 1882 (4226). According to the present invention, the lighter portion of the mineral oil under operation is recovered, and the whole of the remaining portion is saponified or combined with the soap being made, so that on cooling, no oil rises to the surface of the soap. Various distinctive processes are to be adopted, according to the kind of soap required, the mineral oils being brought into a state of fusion, or semi fusion, with an alkali; also with castor oil, and other oils and fats, and with resins, gummy and other matters. Each process will admit of considerable modification, according to circumstances.—E. G. C.

## XII.—PAINTS, VARNISHES, Etc.

*Improvements in Obtaining Compounds of Lead suitable for Making Pigments and for other Purposes.* A. French. Eng. Pat. 5193, November 1, 1883.

THIS invention relates to the treatment of sublimed white lead, or the compound obtained by a process described in a previous specification of letters patent granted to the inventor on June 8, 1881 (2494). In order to obtain "an excellent white pigment requiring very little oil to form white paint, of the consistency of ordinary white lead," the sublimate (formed in the working of the inventor's process), consisting principally of sulphide of lead, is treated with hydrochloric acid, an oxychloride being produced. To obtain a dark red or brown pigment, consisting of peroxide of lead, and a "sulphur compound of lime," a strong solution of bleaching powder is prepared, and the sublimate is gradually added to it with brisk agitation. The chlorine gas evolved may be passed into chambers containing lime, so as to recover the gas as chloride of lime; or it may be made use of in any other way.—E. G. C.

*Anti-fouling Composition Suitable for Ships' Bottoms and other Submerged or Partly Submerged Structures.* W. F. McIntosh and W. S. Crandace, Dundee. Eng. Pat. 5330, November 12, 1883.

THIS invention consists in compounding and boiling together Venice turpentine, tallow, colcothar and Palma Christi oil, with a mixture of barium sulphate and calcium carbonate ground with linseed oil and common turpentine. Various proportions of these constituents may be used, but the following quantities have been found to answer well:—

Venice turpentine and common turpentine .....	3	per cent.
Linseed and Palma Christi oil .....	1	" "
Tallow .....	10	" "
Colcothar .....	20	" "
Barium sulphate .....	20	" "
Calcium carbonate .....	20	" "
Alumina .....	1	" "

The mixture is applicable to ships' bottoms, buoys, floating docks, dredgers, bridge and lighthouse piers, or submerged or partly submerged structures made of iron or steel; and it is heated and applied while hot, over one or more coatings of zinc or white lead paint, preferably the former.—E. G. C.

*Improvements in Compositions for Ships' Bottoms, and in the Method of Applying the same.* W. Day, Blackheath. Eng. Pat. 267, January 2, 1884.

THE inventor first applies to the inside and outside plates of ships, caissons, water tanks, etc., a preparatory coating of crude spirits of naphtha. When the spirit is partly absorbed into the pores of the surface, a second

coating of the following composition is applied. A solution of India-rubber in naphtha is added to a mixture of melted rosin and tar, the proportions of these ingredients being, in general, an ounce of India-rubber, four pints of crude spirits of naphtha, four pounds of rosin, and two pints of coal-tar. To this mixture are added a pound of granulated pitch and a pound of Portland cement, lime, or other similar powder. The last named ingredient may be omitted, but then the composition has less body. The composition is put on with a brush. When desirable—*e.g.*, for the inside bilge bottom plates and rivet heads of ships—a third coating or layer, consisting of hot asphalt, may be applied in addition.—E. G. C.

*Improvements in Paints or Compositions for Coating Ships' Bottoms and other Submerged Surfaces, and for Preserving Iron, Wood, &c., from the Effect of Atmospheric Exposure.* G. J. Andrews and J. E. Sutton, London. Eng. Pat. 5996, April 5, 1884

Two ounces of litharge and 90gr. of mercuric chloride are mixed with a gallon of raw linseed oil, the mixture being gently boiled until the salts are quite dissolved. Four pounds of bitumen and four pounds of the best black pitch are now added, a gentle heat being again applied until the whole is dissolved. When the mass is cold, three pounds of dry red lead is added, and, finally, sufficient spirit of turpentine "to form a good working paint," which paint is to be applied in any ordinary way to the surface to be coated. In certain cases no turpentine need be used, the composition being liquified by heating and applied while hot.—E. G. C.

#### XIV.—AGRICULTURE, MANURES, Etc.

*The Estimation of Nitrogen in Commercial Manures.*  
By P. Wagner. Chem. Zeit. viii. 37, 649.

For the estimation of the nitrogen in ammonia salts the author recommends the use of the azotometer, which is fully described in his "Lehrbuch der Dünger-Fabrikation." The use of about four liters of cooling water is recommended and care should be taken to keep the

solution is then filtered, and 10cc. of the filtrate introduced into the azotometer. The weight of nitrogen found (in grammes), multiplied by 500, when 20grm. of sub. are used, and by 250 if 40grm. are taken, gives directly the percentage of nitrogen. For the estimation in organic substances the author makes use of the soda-lime process. As he has already recommended in a former paper (*Chem. Zeit.* vii. 1475), he uses an iron combustion tube, not only on account of the cheapness and greater ease it affords, but also because it allows of better and more exact results being obtained. It has often been observed that such substances as leather or blood-powder give but very indifferent results with the soda-lime process. The author has always obtained good results with such substances, as the following figures show:—

Sub. Used.	Nitrogen.	Difference from Average.
0.5 .....	13.16 .....	0.13
— .....	13.16 .....	0.13
— .....	13.02 .....	0.01
— .....	13.09 .....	0.06
0.6 .....	12.95 .....	0.08
— .....	12.89 .....	0.014
0.75 .....	12.82 .....	0.11
— .....	13.02 .....	0.01
— .....	13.16 .....	0.13
— .....	12.97 .....	0.06
0.5 .....	13.09 .....	0.06
0.5 .....	12.95 .....	0.08
Average .....		13.03

The following is the complete apparatus used (Fig. 1). It consists of an apparatus for generating hydrogen, a gasometer, and combustion tube with accessories; A is a bell-jar 67cm. high and 10cm. wide, hung in a cylinder 18cm. wide and 65cm. high, filled with dilute sulphuric acid. The bell-jar is closed at the bottom with a perforated lead plate, which rests on two glass rods placed in perforations in the glass; above the lead plate is a layer of fine gravel 13cm. thick, and the rest is filled with granulated zinc. On opening the screw-cock, acid ascends into the bell-jar, the generated hydrogen passing through the U-tube, which is filled with soda-lime, on its way to the gasometer, the construction of which will be clear from the drawing. It is only necessary to remark that the cylinder is weighted with lead at the top to obtain the necessary gas pressure. The wash-

FIG. 1.

whole during the experiment at a constant temperature. For the estimation about 20grm. of ammonium sulphate, or 40grm. of ammonium- or potash-ammonium superphosphate, should be taken, mixed in a liter flask with distilled water, and well shaken for half an hour; the

bottle D is half-filled with water, enabling the gas stream to be observed and regulated by the screw-cock C. The combustion furnace needs no description. The wrought-iron tube which is used is 95cm. long and 17mm. wide, and projects 17cm. in front of and 25cm. behind the

furnace. The ends are closed with India-rubber corks; in the front part of the tube, about 15cm. from the mouth, is placed a 12cm. long layer of coarse and not fused soda-lime held together in front by an asbestos wad, and behind by a piece of iron wire gauze rolled together. This tube will serve for about 100 combustions. The flask G is used to contain the titrated acid which is poured in by way of F, and some part of which is retained by the glass-wool placed there for that purpose, so that no trace of ammonia can pass through. The following is the method used for titrating the excess of acid: A few drops of rosolic acid are brought into G, and soda solution added until red colour is produced, the liquid is then poured into a porcelain basin, then through F back into G, then again into the porcelain dish, and the titration finished; the titrated liquid is then poured through again, and if necessary soda solution added until the reaction is permanent. Should, on account of a colouration of the acid, the colour reaction not be clear enough, a drop or two of acid is added to the titrated liquid, it is then evaporated to dryness on the water bath, and the residue brought with the aid of 10cc. of water into the azotometer. With regard to the filling of the combustion tube, the following is to be said. The substance is mixed in a mortar with powdered soda-lime, and emptied into the copper capsule H, from which it is easily brought into the 31cm. long iron boat I, which, during the operation of filling, is laid in the 34cm. wide copper plate K, thus preventing any loss of the mixture. After the mixture is covered with soda-lime, which has been used for cleaning the mortar, etc., of any mixture that may have clung to it, the iron boat, with the aid of the wire L, is pushed into the combustion tube, the end of which is again closed with the India-rubber cork, the other connections made, and a slow stream of hydrogen passed through, which is kept up during the whole time of the combustion. The tube is heated in the usual manner. The end of the combustion can be readily ascertained by pinching the India-rubber tubing with the fingers, near the screw-cock C, and observing if the acid in G retains its level. If this is the case the gas is turned off, the flask G changed, and the iron boat, as soon as red heat has disappeared, withdrawn by the aid of the wire N, a fresh boat placed in the still hot tube, and a fresh combustion commenced. A chemist with the aid of two furnaces can readily complete 25 combustions a-day. The author now goes on to the estimation of the nitrogen in nitric acid, refers to his former paper (*Chem. Zeit.* vii. 1710), and gives the

high and 14½cm. wide, to receive the etched tubes, after being filled with nitrous oxide. The experiment is conducted as follows: 40cc. of a solution of ferric chloride (containing 200grm. of iron in the liter) is brought with an equal quantity of HCl (20 per cent.) into the flask A. Several cc. of HCl are then placed in the funnel B, the cock opened and the HCl allowed to flow into the flask, care being taken to retain several drops in the funnel, to prevent the admission of air into the flask, the contents of which are then boiled until all the air is driven out. As soon as that is accomplished 10cc. of "normal salt-petre solution" (which contains exactly 35grm. of pure nitrate of soda in the liter, are placed in the funnel and allowed to flow drop by drop into the boiling iron solution. The normal solution is washed through with 20 per cent. HCl, and when this has run through the operation is complete. The etched tube is then changed, the iron solution being kept boiling, and 10cc. of the solution to be analysed (which must be made of such strength as to evolve 50cc. to 90cc. of nitrous acid during the operation) placed in the funnel and allowed to run through in the same way as the "normal solution," it also being washed through with 20 per cent. HCl. The iron solution is sufficient for seven or eight estimations. The graduated tubes having been conveyed to the cylinder here mentioned, which is filled with water of any convenient temperature, the volume of nitrous acid can be read off without the necessity of observing the temperature or the barometer pressure. The calculation is very

FIG. III

FIG. II

following explanation of the apparatus he uses. A is a Berlin flask of 250cc. to 300cc. capacity; B a funnel tube with stop-cock, of about 15cc. capacity, reaching to the centre of the flask, but not touching the liquid in it; C is a glass tube that reaches to the 24cm. wide, 18½cm. high trough D, and which ends below the water level. The opening E of the trough D is for the purpose of conveying fresh water to the trough, and F, which is provided with a tube that reaches 2cm. higher than C, is for the exit of the water. A wire frame is provided for holding the etched tubes. Fig. 3 represents a cylinder 44cm.

simple. Grandeau has prepared a table so that one has only to read off the volume of gas. To prepare the test solution 35grm. of the substance are to be taken and dissolved in a liter of distilled water, and so much of the filtrate taken as evolve at least 50cc. of gas. The results are very exact and reliable, the operation being at the same time very simple. Besides the above methods the author has found Ruffé's method for the analysis of Peru guano very convenient, and recommends the following modifications: Mixture I. is made of 100 parts by weight of powdered soda-lime, with 10 parts of oxalic acid. Mixture II., 100grm. caustic lime with 10cc. pure concentrated  $H_2SO_4$ , the mixture to be preserved in a well-stopped bottle. Mixture III., 100 parts by weight of hyposulphite of soda, dried on the water bath, are mixed in a warm mortar with 100 parts dried soda-lime, eight parts powdered wood charcoal, and eight parts of flowers of sulphur. The mixture is to be poured, still warm, into a flask, the mouth of which is to be closed with an India-rubber cork. For the experiment a 5cm. long layer of mixture I. is brought into a glass tube, 40cm. long and 5mm. wide, closed at one end. Then 15gr. of an equal mixture of Peru guano and mixture II., are mixed with 20gr. of mixture III., and the whole brought into the tube, which is then filled with coarse soda-lime. The rest of the operation is conducted in the usual manner.—F. T. S.

*Report on a Series of Experiments carried out in 1882 at the Kuf Agricultural Station.* Prof. Emmerling, Dr. Loges, and Dr. Metzger. Biedermann's Cent.-Blatt. 1884, 4, 217.

THESE experiments furnish information as to the influence on different soils of soluble and precipitated phosphoric acid in combination with nitrogen, of bone-meal, Peruvian guano, etc. The report contains a long and detailed account of these experiments, together with tabular statements of the various manures employed, their composition, the constitution and nature of the different soils, and the character of the crops obtained. —E. G. C.

*On Sulphuric Acid as a Manure.* H. Fresenius, Stocks, and an unknown Author. Biedermann's Cent.-Blatt. 1884, 3, 160.

THE first-mentioned author considers that, as a rule, sulphuric acid scarcely exercises any influence at all as a manure: only in a soil free from lime and rich in phosphoric acid could it effect the liberation of the latter. Stocks has made some experiments with rye, wheat, and barley, and has shown that, while sulphuric acid appears to induce a very slight increase in the crop, its cost is so considerable that its use is anything but profitable. The third author's observations coincide entirely with those of Dr. H. Fresenius. The consensus of opinion, therefore, seems to be against manuring directly with sulphuric acid. —E. G. C.

*Manuring Barley and Oats with Nitrogen and Phosphoric Acid.* Dr. M. Märcker. Biedermann's Cent.-Blatt. 1884, 3, 162.

DR. MÄRCKER's experiments indicate that nitrogenous manures used alone, such as Chili saltpetre, promote the growth of oats far more than that of barley. On the contrary, phosphatic manures are eminently favourable to the growth of barley, while their effect in promoting the growth of oats is but moderate. —E. G. C.

*On Crude Ammonium Superphosphate as a Manure.* Dr. E. Wollny. Biedermann's Cent.-Blatt. 1884, 3, 167.

THE ammonia contained in lighting-gas has hitherto been absorbed in sulphuric acid, and brought into the market as ammonium sulphate. According to a new process, that of Bolton and Wanklyn, the gas freed from tar is passed into holders containing superphosphate spread on trays. The superphosphate absorbs the ammonia, a dark green or black neutral substance of a penetrating odour being thus formed. This crude ammonium superphosphate contains, according to H. Bunte, 75% of ammonia, and the phosphoric acid is present in it in the precipitated condition. Dr. Wollny's experiments were made with the object of ascertaining the value of the crude superphosphate as a manure, and of settling the question whether the ammonium thiocyanate contained therein would be prejudicial to vegetation. Crude ammonium superphosphate, prepared by Bolton and Wanklyn's process, contains 0.7 to 1.0% of ammonium sulphocyanate; and the author found that this compound, when used in quantity amounting to 500kg. per ha., exercised the same influence on the crops as ammonium superphosphate, free from sulphocyanate, but containing

the same amounts of nitrogen and phosphoric acid. The prejudicial effect of the ammonium sulphocyanate only becomes marked when more than 500kg. per ha. of the impure superphosphate (containing the above-mentioned quantity of sulphocyanate) is employed, and it is observed to vary with different cereals. —E. G. C.

*On the Value of "Markkohl" as Fodder.* Dr. Adolf Mayer. Biedermann's Cent.-Blatt. 1884, 3, 170.

ANALYSES of the stalks and leaves of the three kinds of cabbage, known as green "markkohl," "red markkohl," and ordinary cabbage, furnished the following results:—

#### 1.—STALKS.

	Green.	Red.	Ordinary.
Water.....	87.0	86.7	86.3
Albumen.....	0.9	0.7	0.7
Other nitrogenous substances.....	0.3	0.5	0.5
Fat.....	0.2	0.2	0.3
Carbohydrates.....	7.9	7.9	8.7
Cellulose.....	2.1	2.1	2.6
Ash.....	1.3	1.6	0.9
	100.00	100.00	100.00

#### 2.—LEAVES.

	Green.	Red.	Ordinary.
Water.....	87.0	87.0	86.5
Albumen.....	1.7	1.5	1.6
Other nitrogenous substances.....	0.8	0.7	0.9
Fat.....	0.5	0.4	0.6
Carbohydrates.....	6.9	6.5	8.2
Cellulose.....	1.5	1.6	1.1
Ash.....	1.6	2.3	1.2
	100.00	100.00	100.00

Taking the relative values of albumen, fat, and carbohydrates as being 5 : 3 : 1, the following figures, expressing the nutritive values of the three kinds of cabbage, are obtained:—

	Green.	Red.	Ordinary.
Stalks.....	12.0	11.0	12.1
Leaves.....	16.9	15.2	18.0

—E. G. C.

*Experiments with Potatoes, Beetroots, and Maize, carried out at the Agricultural Station of the Somme.* A. Nantier (Annales Agron. 1882, 9, 193-206). Biedermann's Cent. Blatt. Agrik. Chem. 10, 662.

THE soil chosen was of moderate productiveness, and an average sample yielded, on analysis, the following results:—

Siliceous pebbles, over 5mm.....	25.65
" " from 3 to 5mm.....	2.15
" " 1 to 3mm.....	1.60
Fine earth, under 1mm.....	70.60
	100.00

The air-dried fine earth gave:

Water.....	6.93
Nitrogen.....	0.20
Phosphoric acid.....	0.25
Humus.....	1.06
Carbon contained therein.....	0.61
Potassium.....	0.10
Lime.....	5.97

Although this ground cannot be called poor, as regards its percentage of constituents valuable to plant life, it nevertheless, according to the author, contains only one third of the quantities which a good soil should contain.

*Experiments with Potatoes.*—These were made with four foreign and one German variety. The unmanured portions yielded the following results per ha, for every 1000 kilos. planted:—

Varieties.	Yield in Bulbs.				Containing.				Per ha.	
	Healthy.	Large.	Small.	Diseased.	Dry Substance.	Starch.	Dry Substance.	Starch.	kilos.	kilos.
Sancisse (native).....	2,600	1,710	860	660	21.6	31.5	639	377		
Snowflake.....	2,858	1,608	1,250	112	25.8	18.0	721	510		
Early Rose.....	1,200	2,500	1,700	100	26.2	17.5	1,000	603		
Merveille d'Amerique.....	5,200	3,800	1,100	1,100	22.7	11.6	1,178	760		
Champion.....	11,800	9,100	2,600	100	30.7	19.0	3,630	2,221		

The unfavourable weather of the year in which the experiments were made, had a bad influence upon the results, the yield being only very moderate, and the number of diseased potatoes amounting to as much as one-fifth of the entire crop of two of the varieties—the *Saucesse* and the *Merveille d'Amérique*. It is evident, from the table, that in every particular the *Champion* variety furnished the most satisfactory results; those yielded by the *Early Rose* were also very respectable. Several parcels of the *Snowflake* variety were planted, and differently manured; they were given, in stable manure and peat, 140kg. of nitrogen; in Chili Saltpetre and sulphate of ammonia, 70kg. of nitrogen; in the phosphates, 60kg. of phosphoric acid; and in potassium salts, 45kg. of potassium; in each case per *ha*. The following results were obtained:—

MANURE, Kg. per <i>ha</i> .	YIELD IN BULBS.			
	Total.	Large.	Small.	Diseased
Unmanured .....	kg. 3000	kg. 1008	kg. 1250	kg. 112
Stable Manure ..... 35,000kg.	2856	1466	1230	160
Peat ..... 12,500 „	3410	2410	990	40
Chili Saltpetre..... 450 „	3300	2060	1010	200
Ammonium Sulphate... 366 „	2040	1910	1030	100
Natural Phosphate .... 370 „	2750	2100	590	60
Precipitated Phosphate 300 „	4040	3554	470	16
Superphosphate ..... 400 „	4090	3380	608	96
Potassium Salts .....	2108	1150	908	40

The most noteworthy results are evidently those with the precipitated phosphate and the superphosphate.

*Experiments with Sugar Beets.*—Two kinds were tried, “*Rény*” and “*Vilmorin*.” These varieties were similar to one another, and equally good. The results, with various manures, were as follows:—

MANURE PER <i>ha</i> .	Nutrient in the Manure.	RÉMY.			VILMORIN.		
		Yield.	Sugar per cent.	Sugar per <i>ha</i> .	Yield.	Sugar per cent.	Sugar per <i>ha</i> .
Unmanured .....	—	kg. 28,200	11.7	kg. 3,299	kg. 29,200	11.8	kg. 3,412
Stable Manure ..... 35,000kg.	Nitrogen	34,000	11.0	3,710	31,300	11.5	3,910
Peat ..... 12,500 „		22,200	11.7	2,597	27,400	11.9	3,260
Chili Saltpetre..... 900 „		35,800	11.4	4,081	39,800	11.7	4,616
Ammonium Sulphate ..... 732 „		36,000	11.4	4,068	20,600	11.6	3,549
Superphosphate ..... 710 „	Phosphoric Acid.	45,100	11.3	5,085	49,200	11.4	5,608
Precipitated Phosphate ..... 600 „		45,600	11.2	5,060	48,540	11.6	5,626
Natural Phosphate ..... 800 „		20,300	12.9	3,121	20,320	12.0	2,444
Potassium Salts ..... 200 „		28,000	10.6	2,968	29,200	10.2	2,978

Here, as in the case of the potatoes, superphosphate and precipitated phosphate furnished the best results, proving that the soil was wanting in phosphoric acid; this could be best added in the form of precipitated phosphate.

*Experiments with Maize.*—In consideration of the poverty of the soil, and the vigorous growth of maize, larger quantities of the manures were employed. The results per *ha*. were:—

Unmanured .....	30,000 kg.
Peat, 35,000kg. ....	21,500 „
Potassium Salt, 200kg. ....	29,200 „
Potassium Salt, 100kg. (Peat, 16,500kg.) ..	26,000 „
Chili Saltpetre, 1200kg. ....	36,200 „
Stable Manure, 50,000kg. ....	50,000 „

—E. G. C.

*Experiments on the Influence of Feeding with Ground Cotton Cake upon the Yield of Cows' Milk.* Biedermann's Cent.-Blatt. Agrik.-Chem. 10, 683.

The results of this series of experiments, which need not be given in detail, were communicated to the Agricultural Society of Oldenburg (*Journ.* 1883, 10, 91). On the whole they were decidedly in favour of this mode of feeding.—E. G. C.

*Manuring with Fish* (Landw. Wochenbl. Schleswig-Holstein, 21, 214). Biedermann's Cent.-Blatt. Agrik.-Chem. 10, 703.

This is carried out to a large extent in Western Holstein. Small herrings, smelt, etc., are carefully spread on the ground, both in the spring and autumn, and at once ploughed under; crows and sea gulls carry away considerable quantities. This kind of manure can be applied to fruits, with satisfactory results; potatoes, however, are found to be watery and poor in flavour. The amount of fish used in Holstein for the purpose of manuring, varies very greatly according to the quantity caught.—E. G. C.

*On the Estimation of Reduced Phosphoric Acid.* Gas-send and Campredon (*Ann. Agron.* 1883, 266-269). Biedermann's Cent.-Blatt. 10, 708.

The authors state that, in determinations of phosphoric acid (as ordinarily carried out, by precipitation with magnesia-mixture, ignition of the precipitate, and weighing the pyrophosphate obtained), the results come out 1 per cent. and more too high, the reason being that the precipitate is, under the ordinary conditions, impure, containing, according to the authors, alumina, oxide of iron, lime, magnesia, sulphuric acid, and especially silicic acid. Washing with dilute ammonia will effect the removal of all these impurities, with more or less difficulty, with the exception of the last, which can only be partially got rid of. It is therefore recommended that the precipitate be dissolved in acetic acid and the phosphoric acid titrated with uranium solution.—E. G. C.

*The Value of various Nitrogenous Compounds for Manuring Purposes, and their Influence on the Composition of Oats.* Dr. M. Marcker. Biedermann's Cent.-Blatt. 9, 584.

SEYFFERT made some experiments with turnips, which were grown in boxes, 1 square metre in size, and filled with sand. The plants received equal quantities of manure, the nitrogen being in different forms, and the results obtained were as follows:—

With manure free from nitrogen .....	755grm. of roots.
„ 25grm. of nitrogen in Meijlones .....	710 „
„ „ „ Leather-meal, 4690 „ ..	„
„ „ „ Bone-meal, 15720 „ ..	„
„ „ „ Blood-meal, 16540 „ ..	„
„ „ „ Horn-meal, 20015 „ ..	„
„ „ „ Chili Saltpetre 20075 „ ..	„

These results have received corroboration from the results of some experiments subsequently made by Dr. Julius Albert with the above, and other manures. The composition of the oat is influenced to an important extent by different manures. For example, when fermented leather meal and non-nitrogenous manures have been used, the proteins are from 8.7 to 10.7 per cent.; with Chili saltpetre and sulphate of ammonia, they amount to 11.2 and 11.1 per cent.; while, when bone- and blood-meal have been employed, the albuminoids amount to 13.6 and 11.6 per cent. Variations are also observed in the proportions of straw and mineral matter.—E. G. C.

*Analyses of Volcanic Ashes and Lavas from Etna and Vesuvius.* L. Ricciardi. Biedermann's Cent.-Blatt. 1884, 3, 208.

SPECIMENS of the above were analysed by the author with the following results:—

	VOLCANIC ASHES.		LAVAS FROM ETNA (CATANIA)					
	VESUVIUS.	ETNA.	(IN THE YEAR 1869).					
	FEB. 25, 1862.	JAN. 23, 1862.	a.	b.	c.	d.	e.	f.

—E. G. C.

*Wool Dust.* Dr. J. Nessler (Wochenbl. des Landw. Ver. in Bad. 13, 104). Biedermann's Cent.-Blatt. Agrik. Chem. 10, 705.

THE dust separated during the manufacture of woollen goods consists of fibres of wool intermingled with a fine powder. Dr. Nessler separated these two constituents with the aid of a sieve, determined their quantities, and also the amount of total nitrogen in each sample examined. The following figures were obtained with sixteen samples:—

No.	Fibre per cent.	Powder per cent.	Nitrogen per cent.	Value per Centner m.	No.	Fibre per cent.	Powder per cent.	Nitrogen per cent.	Value per Centner m.
1	—	—	9.68	3.87	9	50.0	50.0	6.53	2.61
2	—	—	5.90	2.36	10	11.0	89.0	3.17	1.27
3	10.0	60.0	5.23	2.19	11	43.0	57.0	5.37	2.15
4	11.3	88.7	2.30	0.90	12	17.0	83.0	2.98	1.19
5	17.1	82.6	3.20	1.28	13	—	—	1.08	0.43
6	17.0	83.0	3.75	1.40	14	29.0	71.0	5.41	2.17
7	7.0	93.0	2.16	0.86	15	11.0	89.0	2.18	1.19
8	23.0	77.0	3.36	1.31	16	—	—	3.45	1.38

No. 1 was extremely clean; Nos. 13 and 16 were greasy, and the amounts of fibre in them could not be correctly estimated. It is evident, from the figures, that the greater the proportion of fibre, the larger is the percentage of nitrogen, and therefore the greater the value of the sample.—E. G. C.

*The Influence of Mineral Substances on Germination.* P. P. Delcraïn and E. Breal. Biedermann's Cent.-Blatt. 9, 618.

ACCORDING to the authors' experiments, among all mineral substances, lime exercises the most favourable influence upon germination. It is not a matter of indifference, however, under what form the lime is presented to the germinating plant; it is much more active when present as a salt of ulmic acid, than when combined with nitric acid. It seems that the ulmic acid acts directly in nourishing the young plant.—E. G. C.

*On Sun-flower Seeds as Fodder for Cows.* Dr. M. Schrodt and H. v. Peter. Biedermann's Cent.-Blatt. 9, 609.

SOME experiments made by the authors have shown that, as regards dietetic value, the use of sun-flower seeds is not disadvantageous; animals consume them with a good appetite, and do not alter in weight. Moreover, fodder containing an admixture of sun-flower seeds is a little cheaper than ordinary fodder.—E. G. C.

*On the Employment of Chili Saltpetre and Sulphate of Ammonium in Beet-root Culture.* O. P. Deherain. Biedermann's Cent.-Blatt, 9, 593.

EXPERIMENTS made at Grignon furnished the following results, from which it appears that the ammonium salt has a prejudicial effect upon the development of the beet, if the soil does not contain sufficient organic constituents:—

1876 (Vilmorin).

	Yield kg.	Sugar kg.
Without Manure .....	17,400	11.5
400kg. Chili Saltpetre .....	19,000	12.7
400kg. Chili Saltpetre+100kg. Superph. ....	21,400	13.1
1,200kg. Chili Saltpetre .....	21,400	12.6
100kg. Ammonium Sulphate .....	16,100	13.0
100kg. Ammonium Sulphate+100kg. Superph. ....	16,100	13.0
1,200kg. Ammonium Sulphate .....	14,000	12.4

1877 (Vilmorin).

Without Manure .....	30,400	19.2
100kg. Chili Saltpetre .....	36,900	17.4
1,220kg. Chili Saltpetre .....	29,800	12.7
100kg. Ammonium Sulphate .....	29,550	17.0
1,200kg. Ammonium Sulphate .....	20,000	16.5

1877 (Vilmorin with rosy tint).

Without Manure .....	46,600	16.2
400kg. Chili Saltpetre .....	56,700	13.3
1,200kg. Chili Saltpetre .....	57,400	10.0
100kg. Ammonium Sulphate .....	41,000	17.3
1,200kg. Ammonium Sulphate .....	37,200	13.4

—E. G. C.

*On the Formation of Milk.* Hans Thierfelder. Biedermann's Cent.-Blatt, 1884, 3, 174.

THE author has made some experiments with the object of discovering the mode of formation and origin of milk-sugar and casein. For this purpose, the lactiferous glands taken from suckling rabbits and dogs, just killed and bled, were washed with brine, dried, and cut up with scissors into a fine pulp. About equal parts of this material were put into four weighed dishes, and the weights determined. Solution of common salt, and blood serum (from the same kind of animal) were then added, and two of the mixtures were now digested on the waterbath, the remaining two being put upon ice. Lastly, all four were treated with warm water, and heated with the addition of dilute acetic acid to coagulate and separate the albuminoids. In the filtrates the milk-sugar was determined volumetrically, the digested portions possessed a distinctly greater reducing power (from 7 to 20 per cent.) than the others. The author concludes, therefore, that milk-sugar is formed by the influence of a ferment upon a substance which he calls "saccharogen." The isolation of this substance has not yet been successfully accomplished, but the author declares it to be soluble in water, insoluble in alcohol and ether, and that it is not destroyed by boiling, and not identical with glycogen. The milk-sugar-producing ferment does not pass into an aqueous extract of the glands, but appears to be bound up within the cells. The experiments on the production of the casein were carried out in a similar way, and it appears that, during the digestion of the lactiferous glands at the temperature of the body, a body is formed, behaving like casein and apparently identical with that substance. Addition of serum-albumen from the same animal promotes the formation of this body, which is probably produced from the serum-albumen by the action of a ferment.—E. G. C.

*On the Influence of Undecorticated Cotton-seed Cake as a Fodder upon Milk-production.* M. Sievert. Biedermann's Cent.-Blatt, 1884, 3, 176.

DECORTICATED and undecorticated cotton-seed cakes differ not only in their composition, but also in their influence when used as fodder. They also have different origins. The undecorticated cakes are prepared chiefly from the entire seed of the Egyptian variety which is imported into England, and there milled. The decorticated cakes are prepared from an American variety, in which the wool is difficult to separate from the husk,

and the kernels of which alone, therefore, are pressed into cakes. The experiments made by the author as to the comparative quantities and qualities of milk furnished by animals, fed, during successive periods of equal duration, with rape-seed cake and undecorticated cotton-seed cake, brought him to the conclusion that the influence of the latter upon milk-production is not a favourable one.—E. G. C.

*On the Value of Wheat Bran as Human Food.* Dr. Max Rubner (Zeitschr. für Biol. vol. xix, pp. 45-100). Biedermann's Cent.-Blatt, Agrik. Chem. 10, 677.

THE bran or husk of wheat, now usually separated from the meal, contains the most essential nutritive constituents in nearly the same proportions as the meal (the protein and fat are indeed somewhat higher); and it has, therefore, been remarked that the separation of the bran from the meal, and its employment as fodder, are causes of a serious loss of food to mankind. A society, called the Bread Reform League, has been recently formed in London, its objects being to teach the advantages of whole-meal bread over ordinary white bread, and to promote the general use of bread prepared from meal ground from the entire grain. Various experiments have been made by the author, with a view of finally ascertaining the answer to this important question, as to whether it is more rational to bake bread from the whole grain, or from the meal after the separation of the bran. Trials were first of all made with different kinds of bread, on man. The bread was made (1) from the finest sort of meal, constituting only 30 per cent. of the corn, which came from Odessa, California and England; (2) from a medium quality made from a mixture of Gika and Minnesota wheat, and representing 70 per cent. of the corn; and (3) from meal prepared from the entire grain—"the wheat-meal flour" of the Bread Reform League. The individual experimented upon (a full grown man) consumed each day a loaf (about 900grm.) of bread, and 1500cc. of beer, the duration of the experiments being three days. The percentages of nutritive material lost with the excrement were found to be as follows:—

	Dry Substance.	Nitrogen.	Fat (Ether Extract)	Carbo-hydrates.	Ash.
Finest .....	4.03	20.07	44.69	4.10	19.28
Medium .....	6.66	24.56	62.83	2.57	30.35
Whole Meal ..	12.23	30.47	51.14	7.37	44.98

From these figures it is plain that the greater the amount of bran in the bread, the greater is the loss of nutritive material, which escapes unused in the excrement. The chief impediments in the way of a complete absorption of the non-nitrogenous and albuminoid substances in coarse-grained bread are, without question, the cellulose walls of the cells constituting the husk. As, notwithstanding that bran bread is less easily assimilated than ordinary bread, the former always contains a not inconsiderable quantity of absorbable nutritive matter, nothing—viewing the question exclusively from the standpoint of its value for the purpose of alimentation—can be urged against the use of bran for human food. It should, however, be ground much more finely than has hitherto been the custom. Viewed from the standpoint of public expediency, the practice of employing the bran in making bread is by no means to be recommended, for the gain in material, which will serve as human nutriment, is only obtained at the cost of depriving our domestic animals of food more easily digested by them than by mankind. The grinding of the whole grain, for human nourishment, must always, therefore, be attended with a certain loss.—E. G. C.

*Experiments upon Quadrannual Rotation.* Dr. A. Voelcker. Journ. Roy. Agric. Soc., Eng., 2nd ser., vol. xix. 224-233.

THE order, as regards manuring and sowing, in the four tracts chosen for the experiments, remained the same in

1882 as in the previous years. The four crops were wheat, barley, clover and turnips. *Rotation No. 1.*—Wheat. The year before this field had yielded white Dutch clover, on which sheep were fed. The seed was sown on October 23, but the ripening was somewhat hindered by rain and want of sunshine during the summer months. The harvest was on August 14; the results were as follows:—

No. of Parcel.	MANURING.	HEAVY WHEAT.		SMALL WHEAT.		STRAW, Etc.
		Kg.	1hl.=kg.	Kg.	1hl.=kg.	
1	Clover on the field eaten by sheep, which received as fodder 305kg. of cotton-cake ....	1125	76.6	53	68.9	2551
2	Clover consumed on the field; fodder 330kg. of maize.....	1133	76.1	11	66.2	2512
3	Clover taken without fodder; in the earlier part of the year as much potash, phosphoric acid, nitrogen, etc., as were contained in 305kg. of cotton-cake .....	1050	75.3	93	68.1	2835
4	As 3; as much nourishment in the form of artificial manuring as was contained in 330kg. of maize .....	1208	75.0	31	63.8	2882

The quality of the wheat from parcels 1 and 2 was better than that from parcels 3 and 4, of which the latter had received a part of its nitrogen in the form of Chili saltpetre. Altogether, the amount of corn yielded in 1882 was considerably less than that obtained in the preceding year, but the quality of the grain was better, and the quantity of straw larger than in 1881. *Rotation No. 2.*—Barley. The turnips grown in 1881 were consumed by sheep, in the spring; the ground was ploughed in the beginning of April, and the barley sown on the 22nd of this month; in the middle of May white Dutch clover was sown among the barley. The latter was cut on September 11. The results obtained per acre were as follows:—

Here, as in the preceding year, parcel 3 (which had received the strongest mineral manure) furnished the highest result.—E. G. C.

*Manuring Experiments.* Dingl. Polyt. Jour. 252, 484. DEHERAIN (*Compt. Rend.* 1884, 1286) has made a series

of experiments extending over a period of four years, and found that one hectare of soil gave the following yields according to the character of the manure:—

	Feeding Maize.	Potatoes.
	Kilos.	Hectolitres.
Sodium Nitrate .....	63,355	276.0
Sodium Nitrate and Superphosphate.....	65,316	311.0
Ammonium Sulphate .....	60,035	290.5
Ammonium Sulphate and Superphosphate. 60,216	278.0	
Without Manure .....	58,300	278.0
Superphosphate .....	58,100	276.0

—D. B.

No. of Parcel.	MANURING.	HEAVY BARLEY.		SMALL BARLEY.		STRAW, Etc.
		Kg.	1hl.=kg.	Kg.	1hl.=kg.	
1	Without Artificial Manure (Cotton Cake Parcel).....	1111	61.9	76	56.4	1716
2	Without Artificial Manure (Maize Parcel) .....	1051	65.8	68	55.5	1705
3	56kg. Chili Saltpetre .....	908	65.0	91	55.1	1821
4	Without Artificial Manure .....	1019	65.1	60	55.1	1686

Here it is evident that parcel No. 1 gave the best result, while Nos. 2 and 4 were nearly equal as regards their produce. *Rotation No. 3.*—White Dutch Clover. The clover was eaten by sheep, of which those on parcel 1 were given cotton cake, and those on parcel 2 received maize. The animals consumed the following amounts:—

Parcel.		Kg.
1	10 Sheep during 88 days, and 5 Sheep during 22 days.....	155
2	10 " " 88 " " 22 " " .....	181
3	10 " " 55 " " 23 " " .....	89
4	10 " " 60 " " 22 " " .....	52

*Rotation No. 4.*—Swedish Turnips (managolds) had previously been reared on this area. Seed sown on June 5th.; harvest in the second week in December.

No. of Parcel.	MANURING. Kg.	TURNIPS. Kg.	LEAVES. Kg.
1	Stable Manure of 610 litter straw, 2268 beetroot, 567 chopped wheat straw, and 154 cotton cake .....

*Apparatus for Pressing and Preserving Green Crops for Ensilage.* By D. B. Chatterton, Chester. Eng. Pat. 1944, January 23, 1884.

Upright girders of T or other suitable section, pass through the silo, and are bedded in a concrete floor. Longitudinal and transverse horizontal pressing girders are arranged to slide up and down the uprights as guides, and are covered with planks tongued with hoop iron, forming a watertight roof or cover to the silo. This cover is raised and lowered as required by means of screw jacks placed on the top of the cover, and secured by grips to the uprights at will. When the cover has been raised by the jacks to the height of the grip, the

cover itself is made to grip the uprights, and the jack grips are shifted higher up, the cover being thus raised by successive steps to the height required. Similar means are adopted for lowering the cover, and for exerting pressure on the ensilage.—J. M. H. M.

*On Manure made from Peat Fibre.* M. Fleischer. Biedermann's Cent.-Blatt. 1884, 3, 210.

ANALYSES of three samples in the raw state, and in the dried condition, yielded the following results:—

	Raw.	Dried.	Raw.	Dried.	Raw.	Dried.
Water .....	865.30	—	698.5	10.0	714.3	—
Fixed constituents .....	131.70	1000.0	301.5	—	285.7	1000.0

—E. G. C.

*Improvements in Preparing Blood for Use as Manure.* W. G. Strype, Wicklow Chemical Works, Ireland. Eng. Pat. 787, January 5, 1884.

THE original claim stood thus: Treating blood by means of a solution of sulphate of alumina or alum, *sulphate of iron or analogous materials* substantially as hereinbefore described. In the amended specification the words italicised are struck out.—J. M. H. M.

*Manufacture of Artificial Manure.* F. W. Martino, Arundel Street, Sheffield. Eng. Pat. 2354, January 29, 1884.

BASIC cinder from the Gilchrist Thomas process is roasted with alum cake, sal enixum, or other material containing free sulphuric acid. A further portion of the basic cinder is roasted without any addition. Raw sewage is precipitated in a tank by the addition of the roasted mixture of cinder and alum cake in suitable proportion, the precipitate allowed to subside, and the clear liquor run off into a second tank. In this tank it is boiled, neutralised with basic cinder, the precipitate allowed to subside, and the liquid run off into a third tank, in which it is rendered distinctly alkaline by the addition of basic cinder and quicklime, again boiled, the precipitate allowed to subside, and the clear liquid run off, filtered through filter beds of raw basic cinder, and discharged into a river or stream. The three precipitates obtained as above are mixed in certain proportions, treated with sulphuric acid until slightly acid, powdered, and sold as manure. Instead of boiling the liquid a second time, as above described, the third precipitate may be obtained by the addition of a mixture of ground and calcined slag, caustic lime, bleaching powder, and animal charcoal.—J. M. H. M.

*Improvements in making Butter, and Apparatus therefor.* Haseltine, Lake, & Company, Southampton Buildings, London. Communicated by Th. Filter Company, Paris. Eng. Pat. 3163, February 12, 1884.

INSTEAD of freeing the butter from buttermilk and water by washing and working, as generally practised, the butter, as soon as formed, is placed in a muslin or wire bag, which is rotated in a centrifugal machine at a high velocity for five or six minutes. The butter is then

removed and kneaded just sufficiently to form it into a compact mass. A drawing of the centrifugal machine is given.—J. M. H. M.

*Improvements in Preparing Lime for Agricultural Purposes.* Isaac Brown, India Buildings, Edinburgh. Eng. Pat. 10,004, July 10, 1884.

QUICKLIME intended for agricultural use is ground to a fine powder instead of being slaked with water. It is intimately mixed with the soil by means of a distributor attached to the plough.—J. M. H. M.

*Manufacture of Chemical Manures.* By J. Mactear, Glasgow. Eng. Pat. 11,127, August 11, 1884.

THE phosphatic, or other material, and the sulphuric acid being mixed together in a trough by rotating paddles in the usual manner, the mixture is delivered (instead of into a storing pit) on to a drying bed artificially heated, and is gradually moved forward over the surface of this bed by means of an endless chain armed with prongs. At the further end of the drying bed the manure is delivered into a trough furnished with a rotating screw blade, which carries the mixture to a "peg" mill, by which it is finally pulverised and delivered into sacks in a finished condition. A drawing is appended.—J. M. H. M.

*Treatment of Phosphatic Substances for the Manufacture of Fertilisers.* By O. Imray, 28, Southampton Buildings, Chancery Lane. Communicated by F. L. Harris, Baltimore, U.S.A. Eng. Pat. 11,191, August 12, 1884.

A SOLUTION containing nitrogenous organic matter is obtained by subjecting bone, hoof, horn, leather, hair, animal or fish offal, etc., to the action of water in a closed vessel at a temperature of 250-350° F. The insoluble residue of this operation is separated from the liquid, dried, ground, and sold as manure. The liquid, enriched with nitrogenous matter, is then used for the treatment of native phosphates, phosphatic guano, marl, marine shells, etc. The phosphatic material is placed in the liquid and subjected to a temperature of 250-350° F., as before. When sufficiently impregnated with nitrogenous matter, it is dried and pulverised. Drawings of a pressure boiler are supplied.—J. M. H. M.

*Producing Economically Concentrated Assimilable Phosphates for Manure, and Soluble Phosphates for the Preparation of Phosphoric Acid and Phosphorus.* By Michael Cahen, Brussels. Eng. Pat. 11,337, August 16, 1884.

THE inventor proposes to substitute carbonic acid for sulphuric acid in the preparation of precipitated phosphate of lime for use as manure, and of soluble phosphate of lime for use in the manufacture of phosphorus. The carbonic acid to be employed is dissolved in water under considerable pressure (50 atmospheres), and this solution

is caused to act upon the phosphatic mineral until the whole of the phosphate of lime and carbonate of lime in the mineral shall have gone into solution, as monocalcic phosphate and calcium bicarbonate, leaving behind the insoluble gangue. The inventor states that on removing the pressure from a solution so obtained, carbonate of lime is precipitated, whilst monocalcic phosphate remains in solution, and the excess of carbonic acid employed is recovered. Further, that if the mixture thus obtained be heated to 100 °C., the precipitated carbonate of lime is decomposed, more carbonic acid evolved, and precipitated tribasic phosphate of lime produced. The specification contains elaborate calculations, based upon the chemical equations supposed to be involved, and all the quantities are calculated upon the scale of equivalents in which O=100. Drawings are appended.—J. M. H. M.

*Improvement in Manufacturing "Cerealine," a Product obtained from Indian Corn.* I. Franklin Gent, Columbus, Indiana, U.S. Eng. Pat. 12,186, September 9, 1884.

THE inventor claims the several steps of his improved process, which are—First, steaming the maize just enough to soften and toughen the hulls and germs; second, coarsely grinding or breaking the steamed corn, and separating the hulls and fine meal from the ground or broken material; third, picking the germs from the coarse, starchy particles; fourth, steaming the thus cleansed starchy particles; and, fifth, pressing and drying the steamed starchy particles to reduce them to thin flakes. A drawing and description of a mechanical picker or germ extractor are given. By this improved process, "cerealine" can be made and sold at prices which make it available for distilling as well as for brewing and edible purposes.—J. M. H. M.

## XV.—SUGAR, GUMS, STARCHES, ETC.

*The Circular Polarisation of Cane-Sugar.* B. Tollens. Ber. 17, 1751-1757.

MEASUREMENTS by the author and by Schmitz (1876) showed that sugar and a number of other substances possess a greater rotary power when examined in dilute solution, than in strong. But as the strength of the solution is decreased, so does the experimental error make itself more and more felt, and as the apparatus then available was far inferior to that now obtainable, it appeared necessary to repeat these determinations with all possible accuracy. After describing the arrangements and apparatus used, a table is given showing the results obtained in examining eleven solutions containing from 1.1062 to 67.4507 per cent. of pure cane-sugar; 43 complete measurements were made, each the mean of twenty readings. The mean specific rotations (a) D of these solutions is 66.4°, and none of the determinations differ from this mean, by more than the error due to the observation.—H. B.

*Circular Polarisation of Dextrose.* B. Tollens. Berichte der Deutsch. Chem. Gesellsch. 17, 2231.

THESE experiments were undertaken with an improved apparatus of Landolt-Laurent, to prove whether the specific rotation of dextrose increases for (a) D, as some think, with solutions of a less concentration than 10 p.c. The dextrose was purified according to the method of Soxhlet, by crystallisation from water and alcohol, and dried directly before use from three to five hours, at 100° for series 1 to 7, and at 60° to 70° for series 8 and 9. The results obtained show that the specific rotary power

increases with the concentration, and corresponds with the author's previous formula for dextrose-hydrate:

$$(a) D = 47.92541^\circ + 0.015334 P + 0.0003883 P^2.$$

The old formula for anhydrous dextrose being:

$$(a) D = 52.71795 + 0.018796 P + 0.00051683 P^2.$$

The following table gives the author's results:—

1. No. of Solution.	2. Percentage Composition	3. (a) D	4. (a) D Calculated		6. Difference between Col. 3 and 4.
		Found Degrees	Old Formula Degrees.	New Formula Degrees.	
4	1.4978	52.107	52.750	52.532	-0.125
8	1.7933	52.289	52.755	52.537	-0.248
2	2.0133	52.073	52.760	—	—
5	2.7333	52.379	52.771	52.556	-0.186
9	7.0012	52.691	52.891	52.673	+0.018
1	10.0272	52.433	52.958	—	—
7	10.0992	52.738	52.960	52.742	+0.004
3	10.2367	52.636	52.965	52.747	-0.111
6	17.3882	52.991	53.209	52.991	-0.000

It appears, therefore, that the amount found, and that calculated from the author's formula, agree very closely; the former, however, being somewhat too low. The following formula is therefore given as being a close approximation to the truth. For anhydrous dextrose:

$$(a) D = 52.50^\circ + 0.018796 P + 0.00051683 P^2.$$

For dextrose hydrate:

$$(a) D = 47.73^\circ + 0.015334 P + 0.0003883 P^2.$$

These formulae are correct for all concentrations from 1 to 100 p.c., and an increase of rotary power for 1.2 p.c. solutions does not exist.—J. B. C.

*An Improvement in the Strontia Treatment of Saccharine Liquors and Apparatus for that Purpose.* John Inury, London. Eng. Pat. 1999, January 23, 1884.

WHEN anhydrous strontia is applied directly to saccharine liquors, the heat developed is so great that the operation is virtually impracticable. To overcome this difficulty anhydrous strontia is first mixed with moist hydrate of strontia; great heat is evolved, by which much of the water is driven off, and there results a monohydrate or low hydrate of strontia, which is well adapted to the treatment of saccharine liquors. The apparatus in which this treatment is effected consists of a strong closed vessel, having, a little way from the bottom, a finely perforated screen, and having supported near the middle of its height a grating. The lower part of the vessel is charged with the saccharine liquor, and the strontia, prepared as above, is placed on the grating. By means of steam the liquor is heated and agitated, until it gradually combines with the strontia, forming a sacrate. The sacrate is more insoluble if a steam pressure of one or two atmospheres be used. When the reaction is complete the steam is turned off and valves are opened to reduce the pressure, and to equalise the pressure in the top and bottom portions of the vessel. The precipitated sacrate settles on the screen at the bottom, and the liquid is drawn off; the precipitate is now washed with water, preferably containing strontia to prevent the solution of any sacrate. By concentration and cooling of the mother and wash liquors, the excess of strontia is recovered in the form of crystallised hydrate.—A. J. K.

*An Improved Method of, and Apparatus for, Treating Sugar-cane Preparatory to the Extraction of Sugar therefrom.* W. R. Lake, London. Communicated from E. Schulze, Amsterdam. Eng. Pat. 13,940, October 21, 1884.

By a specially constructed cross-cutting machine the sugar-canes are first cut into short lengths, about four to five inches long; these pieces are next cut into thin slices by a machine essentially the same as those which are used for preparing beet-roots for the diffusion process. The sugar can now be extracted from the canes by the diffusion process in a manner exactly similar to that which is well known in the case of beet-roots.—A. J. K.

## XVI.—BREWING, WINES, SPIRITS, Etc.

*On the Methods of Cleaning Beer Pumps.* By Kohlmann. Chem. Zeit. viii, 60, 1078.

DIFFERENT views are held with regard to the agents to be used in the cleansing of beer pumps, and opinion seems principally divided between steam and alkaline solutions. Experiments conducted by the author show that the steam process does not always sufficiently do the work required, while very good results were obtained with a cold 2° solution of caustic soda. This latter method is also cheaper than that of steam.—F. T. S.

*Making and Preserving an Extract of Hops or other Aromatic Products, without losing the Flavour.* J. Armstrong, London. Eng. Pat. 71, January 1, 1884.

THE preparation of the extract is to prevent the escape of the aromatic principle of the hop. The hops are infused with water or any other suitable liquid in a closed and jacketed vessel at a temperature of 160° F., which is gradually raised to 200 F. or thereabouts, infusion being continued for about forty minutes. A second and similar infusion is then made, the two products being mixed together. To the infusion there is then added syrup of invert sugar, glucose, or wort, all of which possess the well-known property of preserving the aromatic properties of the hop. The patentee claims generally the preparation of the extract as above described.—C. C. H.

*An Improved Portable Distilling Apparatus.* W. Hood, Seacombe, Cheshire. Eng. Pat. 2445, January 31, 1884.

THIS specification describes a portable form of distilling apparatus suitable for the use of wine merchants. It consists of a small boiling vessel, over and attached to which is a vessel containing the condensing worm, and attached to the upper part of this again is a reservoir for the cold condensing water. The boiler is heated by a self-contained gas burner of the usual construction. The patentee claims the combination of the different parts of the whole apparatus and its construction.—C. C. H.

*An Improvement in the Production of Malt.* H. J. Hadden, London. Communicated by H. Hackman, Bavaria. Eng. Pat. 2468, January 31, 1884.

IN the germination of grain for the production of malt in the usual way, the exterior grains in the heaps of barley become dry, and do not therefore properly germinate. In order to avoid this the patentee sprinkles the exterior of the heaps with a spray produced by means of compressed air, which furnishes their exteriors with enough moisture to prevent contact with the air, and not too great in quantity to injuriously affect proper germination. The claim is made as and for the purpose described.—C. C. H.

*Improved Applications of the Residue Produced by Distilling Wine.* J. C. Mewburn, London. Communicated by H. Crot, Paris. Eng. Pat. 2678, February 4, 1884.

THE residues from the distillation of wine in the production of brandy usually called "vinasse" possess

no value, because their flavour has been totally changed by the operation of distillation. In order to obviate this, this patent proposes that the distillation of the alcohol should be conducted in vacuo at a temperature not exceeding 15° C. After the elimination of the alcohol the vinasses can be evaporated to a syrup which, retaining the properties of the original, can be employed for mixing with low wines to give them body and flavour. It may also be made into a beverage by adding a solution of sugar and bottling. The patentee claims—(1) the utilisation of the residues by distilling at a low temperature as described; (2) the manufacture and production of non-alcoholic beverages as described.—C. C. H.

*An Improved Manufacture of Non-alcoholic Beverages from Grapes or other Fruit.* A. C. L. Weigel, Brighton. Eng. Pat. 8132, May 23, 1884.

THE object of this invention is the production of a beverage possessing all the properties of wine prepared from the grape, but at the same time being non-alcoholic. After fermentation in the usual way the must is distilled in vacuo at a temperature not exceeding 160° F., the ether being collected separately from the alcohol. The residue from distillation is cooled in a closed vessel out of contact with the air and refrigerated by ice, the ethers are added and also a certain proportion of syrup made by evaporating unfermented grape juice; this may then be filled into bottles for consumption. If a sparkling beverage is required the same liquid may be bottled saturated with carbonic acid gas in the same way as aerated waters. The claim is for the manufacture of non-alcoholic fermented beverages substantially as described.—C. C. H.

*Liquid Hop Auxiliary.* F. W. E. Shrivell, London. Eng. Pat. 10,427, July 22, 1884.

THE liquid hop auxiliary consists of an extract prepared from quassia, chiretta, columbia root, gentian root, camomile flowers, cinchona bark, or any other vegetable bitter, and mixing it with tannic acid, or any substance capable of precipitating albumen, and a certain proportion of hops. The extract may be prepared by any of the usual well-known means, and the object is to produce a liquid which can replace hops in brewing, or for any such analogous use. The claims are: (1) The hop auxiliary or liquid as described; (2) the preparation of the same in a liquid and not in a solid form.—C. C. H.

## XVII.—SANITARY CHEMISTRY, DISINFECTANTS.

*Purification of Water.* Wm. Anderson, Westminster. Eng. Pat. 5496, November 23, 1883.

THIS invention relates to the purification of water by means of spongy iron. Its objects are:—To preserve the purifying agent in an active condition by keeping its surfaces clean and free from the slimy matter removed from the water, and also to avoid the use of the very large quantities of the material necessary in percolation methods and the expense consequent thereon. To effect these objects, the spongy iron is kept continually in a state of motion, and made to fall through a stream of the water passing through the purifying apparatus. The apparatus consists of a cylinder suspended on hollow runnings, which serve as inlet and outlet respectively for the water operated upon. The cylinder is capable of being rotated, and its interior periphery is provided along its whole length with projecting shelves or ledges, so that the spongy iron introduced into its interior, during rotation, carried upwards, and falling from the shelves passes through the current of water running through the cylinder, thus effecting by its intimate contact the required purification. The process is therefore continuous. The respective ends of the cylinder opposite the runnings, serving for inlet and outlet, are provided with a deflecting plate to avoid the disturbance of the spongy iron, and a strainer plate, so that it cannot be carried away by the force of the current. The purified water is finally exposed

to the air to oxidise the iron entering into solution, and filtered through a sand filter. The novelties claimed are (1) the process of purification of water by its passage through a revolving cylinder containing spongy iron; (2) the apparatus substantially as described.—C. C. H.

*Treatment of Sewage.* F. Herbert, London. Eng. Pat. 3850, December 24, 1883.

IN order to effect the deodorisation of sewage of all kinds, and in its entirety obtaining therefrom valuable manures, and for the utilisation of the gaseous bodies given off during treatment, the patentee proceeds as follows:—The sewage is collected in tanks in which, by subsidence, it is deprived of such useless mineral matter as road detritus, &c.; self-acting syphons fitted to these tanks periodically transfer their contents into a series of receivers fitted with carbon electrodes, connected with a dynamo electric machine furnishing a current of large quantity, but low intensity. The gases liberated by electrolysis are collected and burned for furnishing steam power, and after being carburetted used for lighting. The thin mud obtained by electrolysis is evaporated down by a gentle heat in a suitable drying apparatus, yielding a highly valuable manure. The patentee claims (1) the use of electricity for the purpose of treating sewage; (2) utilising the gaseous constituents; (3) the combination and arrangement of the apparatus.—C. C. H.

*Improvements connected with Filters for Water and other Liquids.* F. Grosvenor, Glasgow. Eng. Pat. 1415, January 14, 1884.

A FILTERING vessel is formed of an outer carbon crust, made by cementing coke or carbon with tar or resin, and baking the same for some hours, the hollow interior being filled with loose finely-ground animal charcoal. The end is provided with an earthenware cup for fixing the carbon chamber in a filtering vessel. The specification claims the composite carbon filtering block as described.—C. C. H.

*Apparatus for Withdrawing and Filtering Water or other Liquid contained in a Vessel or Receptacle.* P. Garton and J. Garton, Golborne, Lancashire. Eng. Pat. 1391, January 17, 1884.

IN order to withdraw and filter a liquid from a vessel at the same time, the following apparatus is described. A siphon tube is furnished in its longer limb with a cock, and provided at the end of the shorter limb with a filtering vessel, which is funnel-shaped, and divided into two parts by a perforated diaphragm. The upper portion contains animal charcoal, or any other filtering media, and the lower part is filled with sponge, secured in place by a screwed plate. The filtering chamber is placed in the liquid to be operated upon, and the syphoning established by lowering the free end of the tube and exhausting the air. The patentees claim the combination of a siphon tube with a filtering chamber for the purpose described.—C. C. H.

*Improvements in Filters.* W. N. Wilkinson, Manchester. Eng. Pat. 1791, January 21, 1884.

THE improvements herein specified refer to those filters used for purifying water for a domestic supply, and also more particularly to pocket filters. The object is to so arrange the filtering material that it shall be under compression during filtration. The general form of the improved apparatus is as follows:—A top and bottom plate, the latter being fitted with a tube passing through the upper plate. The tube is fitted with a compression spring and loose washer; between the two plates there is secured a helical roll of perforated metal covered with cloth, the interior filled with animal charcoal or other suitable filtering material. A thumb screw at the top, acting upon the spring, presses upon the charcoal and at the same time compression is also exerted upon it by the perforated outer covering. The exterior, in some in-

stances, is covered with India-rubber, which serves to regulate the supply of water to the interior of the filter and also keep it clean on the exterior. Different modifications of the apparatus are also described. The patentee claims under four heads the various details specified.—C. C. H.

*Producing Mixtures of Liquid Acids and Dry Powders for Use with Disinfectants, and as Absorbent Materials for Ammonia.* D. Urquhart, Westminster. Eng. Pat. 221, January, 1884.

SULPHURIC or other fluid acid is mixed with infusorial, or other absorbent inert earth, in proportions to preserve the condition of a powder. This acid powder is mixed with chloride of lime, dry sulphites, or potassium chlorate, for use as disinfectants. The acid powder is also used for cleaning brass, etc., or for absorbing ammonia from furnace gases. The acid powder is said to be sufficiently devoid of corrosive properties to be packed in iron or wooden cases.—C. H. B.

*Improvements in Appliances for Filtering Water and other Liquids.* J. P. Jackson, Liverpool. Eng. Pat. 7347, May 5, 1884.

THE apparatus described consists of an exterior vessel of a cylindrical or other shape, acting both as a receiver for the filtered material, and also as a holder for the remaining parts of the apparatus. The interior of the receiver is fitted with a similarly shaped vessel, conical at its lower extremity, which is perforated along a portion only of the conical surface either with fine holes or oblong slots, and is provided at its conical extremity with an asbestos cloth cover fitted thereto. A second long conical vessel projects downward into the filtering vessel as above described, provided at its lower extremity with a projecting rim to check the rush of the liquid poured into the filter. The first portions of the liquid poured in may be mixed with paper pulp, animal or vegetable charcoal, &c., for the purpose of securing both a fine filtering surface on the asbestos cloth as well as a purifying effect; or the lower part of the conical filter may be packed with animal charcoal. The claims are: (1) the funnel provided at its lower extremity with the projecting rim; (2) the chamber partly conical, with perforated and solid walls carrying the asbestos cloth; (3) a pocket filter of similar construction to the above.—C. C. H.

*Improvements in the Production of Vegetable Carbon for Hygienic, Electrical, and similar purposes.* A. F. Westerlund, Stockholm, Sweden. Eng. Pat. 11,322, May 21, 1884.

FOR the production of a slow-burning carbon, suitable for insulating, preserving, disinfecting, and hygienic purposes, the inventor uses straw, hay, paper, cork waste, cotton sphagnum, and other vegetable materials, which he treats with a solution of boric acid or a soluble borate before carbonisation. Owing to this preliminary treatment, the carbonisation may be effected by free access of air. In a patent application bearing even date with this specification, a similar mode of producing a slow-burning carbon is described, only that the solutions used are made with phosphoric acid or phosphates. The inventor, however, wishes it to be clearly understood that a slow-burning carbon having the same properties as that obtained by the above-described method may be produced by the use of mixed solutions of phosphoric and boric acids or phosphates and borates.—D. B.

## XIX.—PAPER, PASTEBOARD, Etc.

*Effect of Mineral Matter on the Properties of Paper.* Prof. Hartig. Dingler (252), Heft 6.

THE paper used was a resin-sized straw paper, without added mineral matter, with 2.05 per cent. of ash; one square metre weighing 259grm. The same paper when

hotpressed weighed 264grm. per square metre. The same, with an addition of 15 per cent. gypsum, has 17.2 per cent. ash, and weighed 239grm. per square metre. The paper by hotpressing increased—

In absolute rigidity .....	94 per cent.
In tenacity .....	65
In the modulus of the work of tearing 16.5 ..	66

On the other hand, it lost by the addition of 15 per cent. of gypsum—

In absolute rigidity .....	31.2 per cent.
In tenacity .....	23.1
In specific work of tearing .....	47.1

Through the addition of 15 per cent. of gypsum, the resistance to tearing is reduced to about a half.—F. L. T.

*Manufacture of Pulp, etc.* George Boulding Walker, Eng. Pat. 5306.

THE inventor separates the fibre from different species of Yucca by means of specially constructed teasing machines, descriptions and drawings of which are given. The isolated fibre is then treated with chlorine solution or chlorine gas. It may afterwards be boiled in dilute alkali, and further treated with weak chlorine solution.

—G. J. B.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES.

*Alkaloids of Nur Vomica. Some Experiments with Strychnine.* By W. A. Shenstone, Lecturer on Chemistry in Clifton College. Abstr. Proc. Chem. Soc. 1884-5 [1.]

IN continuation of his experiments on strychnine, the author has studied the action of bromine upon the alkaloid, and also the action of nitric acid on bromostrychnine and upon strychnine itself. Strychnine can be readily and entirely converted into the monobromostrychnine of Laurent by the addition of bromine to a solution of strychnine hydrochloride in about fifty times its weight of water. The properties of monobromostrychnine are given. The resinous product obtained by Laurent, which is apt to be the chief product obtained by his method, is found to be a dibromide of the above monobromostrychnine; it has the formula

By the cautious addition of a solution of bromine in chloroform to a solution of monobromostrychnine in the same liquid, a resinous compound is obtained, which is probably dibromostrychnine. On treating bromostrychnine and also strychnine itself with strong nitric acid, besides the nitrostrychnines of various observers, a fair amount of 1:2:4:6 trinitrophenol is produced. This last observation is of importance, as it shows the presence in strychnine of a benzene-ring of carbon-atoms, and probably also of at least one hydroxyl-group, the latter inference being confirmed by the behaviour of strychnine with alkaline oxidising agents.—W. S.

*On the Physiological Action of Brucine and of Bromostrychnine.* By Dr. T. Lander Brunton, F.R.S. Abstr. Proc. Chem. Soc. 1884-5 [1.]

THE difference between the effect of brucine and strychnine appears rather to be one of degree than of kind, and to be chiefly dependent on the more ready elimination of brucine. Like strychnine, brucine produces death by convulsions and not by paralysis; but like curare, it is innocuous when taken into the stomach, though fatal when injected under the skin. Bromostrychnine has an action very much like that of strychnine.—W. S.

*On the Formation of Pyridine Derivatives.* By H. v. Pechman and W. Welsh. Abstr. Proc. Chem. Soc. 1884-5 [1.]

IT is pointed out that nothing is as yet known of the character of the changes which occur in plants and

which lead to the production of the alkaloids, and that it has not hitherto been possible to produce alkaloids by reactions taking place under ordinary conditions of temperature. In coumalic acid, discovered by one of the authors, and obtained by treatment of malic acid with sulphuric acid (*Lhr.* 1884, 936), however, a body has been discovered which at once reacts with aqueous ammonia even at the ordinary temperature, forming hydroxynicotinic acid,

an acid which stands in close relation to the alkaloids. The method of preparing hydroxynicotinic acid and its properties are described, its constitution is fully discussed, and an account is given of its conversion into chloronicotinic and nicotinic acids. Reference is then made to the action of primary amines on ethereal salts of coumalic acid. Aniline and the methyl salt give the acid methyl salt of coumalanilic acid,

which is converted by boiling with sodium hydroxide solution into sodium phenoxynicotinate,

a remarkable change, as it involves the "passage of phenyl from nitrogen to oxygen." The same remarkable isomeric change takes place when the product of the action of methylamine on methyl coumalate is similarly treated, methoxynicotinic acid being formed.

—W. S.

*The Santonine Industry of Turkestan.* By C. O. Cech, Moskau. Dingl. Polyt. Journ. 253 (11), 474.

IN the town of Tschentek, in Turkestan, a large works is being at present erected for the manufacture of santonine from worm-seed. The seed of the plant (*Artemisia Santonica* and *Martiana*), which in large quantity is exclusively found in the valley of the Ariss, contains from 1.8 to 2.3 per cent. santonine. More than 1600 tons of the plant are annually consumed, partly in the raw state and partly after conversion into santonine, of which 1kg. is worth from £2 to £3. The manufacture was carried on up to the present by three works in Germany and one in England, which obtained their raw material at a considerable expense for carriage from Turkestan. Since 100kg. of worm-seed yield about 2kg. of santonine, the new works, situated at the place where the raw product is found, will work under the most favourable conditions, and their make will evidently come into the market at a price to exclude the competition of European makers. As a matter of fact, two German works have already resolved upon discontinuing the manufacture of that commodity. The new works will cost £65,000, and are large enough to work up 1600 tons worm-seed—i.e., to make 32,000kg. santonine. The residues of the manufacture, formed into bricks, will be used as fuel for boilers and houses. The works are nearly finished, and it is intended to commence manufacturing in October, 1884.—S. H.

*Manufacture of Salicylic Acid.* Theodor Kempf, Berlin. Eng. Pat. 5582, November 30, 1883. Provisional protection only granted.

IF diphenyl-carbonate be heated with phenol sodium in a closed vessel, provided with an agitator, for about six hours at a temperature of 100° to 170° C., basic sodium salicylate is formed, and free phenol and diphenyl-ether are liberated. The basic salicylate can then be treated in the ordinary manner, for the liberation of the acid, by treating its aqueous solution with hydrochloric acid.

—C. C. H.

*Manufacture of Salicylic Acid, etc.* J. H. Johnson, London. Communicated by Otto Leupold, Stuttgart. Eng. Pat. 5628, December 4, 1883.

THIS invention deals with the manufacture of salicylic acid, which it effects by causing alcoholic carbonic ethers to react by decomposition upon combinations of sodium

and phenols, either with or without mixture with sodium hydrate or sodium alcoholate. If one equivalent of ethyl carbonate be heated with two equivalents of phenol sodium in a closed vessel, at a temperature of 120 to 150 °C., basic sodium salicylate is produced and alcohol and phenetol distilled off; similarly, ether, carbonic ethyl phenol sodium and sodium hydrate give alcohol and basic salicylate of soda, and in the case of alcoholate of soda ethylic ether is also produced. The basic salicylate of sodium is decomposed by precipitating the salicylic acid by means of a mineral acid. The patentee claims as novel, the production of salicylic acid by heating carbonic ethers with phenol, sodium compounds thereof, hydrate of soda or alcoholate of soda. —C. C. H.

*Quinine Alkaloids.* P. Gacoso, Eng. Pat. 1472, January 15, 1884.

THE inventor has discovered that the alkaloids of Peruvian bark occur in plants of the genus *Artemisia*, from which they can be extracted either in the ordinary manner or according to the following method:—The fresh or dried flowers and seeds, together with the whole plants (the best is *Artemisia Abrotanum* Linn.) must be chopped fine and digested in diluted acid (sulphuric hydrochloric acid, etc.). The extracts obtained by the diluted acid are neutralised, and precipitated by a base. From the filtered moist basic mixture, the alkaloids are obtained by heat with schist oil, coal oil or petroleum having a low boiling point, or by means of alcohol. In the latter case the alcohol must be distilled off, the residue must be treated with diluted acid, and the alkaloid precipitated by means of carbonate of soda or another base. From the solution in the hydrocarbons the alkaloids can be transformed into salts by means of acids, and separated afterwards by means of carbonate of soda, or another base. —F. L. T.

*Apparatus for preparing Oxygenated Air.* By G. F. Redfern. Communicated by Anton Stamm, Leadville, Colorado. Eng. Pat. 8285, May 27, 1884.

THE inventor makes use of two air-tight water tanks, and two nitrogen tanks, in conjunction with an air compressor of any description. By means of an arrangement of slide valves, actuated by any suitable motive power, the air compressor forces air alternately into each of the two water tanks, and at the same time removes the air impoverished in oxygen by its passage through the water into the two nitrogen tanks, also alternately. At every stroke, therefore, air rich in oxygen is being delivered from one or other of the water tanks, and air poor in oxygen is being stored in one or other of the two nitrogen receivers. To increase the percentage of oxygen, the air as delivered from the water tank is passed through a second similar, but smaller, apparatus. The claims are for such an arrangement of slides, or other valves, in conjunction with the tanks as will render the operation automatic. —J. M. H. M.

## XXI.—EXPLOSIVES, MATCHES, Etc.

*Novelties in the Manufacture of Explosives, Blasting Materials, etc.* Dingl. Poly. Jour. 254, 110.

A ELASTIC material called hellhoffite was shown at the Berlin Hygienic Exhibition, of 1883; this compound is prepared by Hellhoff, of Mayence, and consists of diinitrobenzol and nitric acid. The constituents are mixed in the apparatus shown in Fig. 1. A cartridge is represented in Fig. 2, and the funnel used for filling the cartridges is seen in Fig. 3. C. H. Wolff recommends a process for the estimation of nitrogen in nitro-compounds, which is easily carried out, and is an amplification of the Champion-Pellet and Hefs method. In a small decomposition flask *z* (Fig. 4), 0.10 to 0.14 gm. of nitroglycerine or blasting gelatine, or 0.15 to 0.18 gm. of dynamite, is placed, together with 50 c.c. of a previously boiled and again cooled concentrated solution of chloride of iron and hydrochloric acid.

Carbonic acid gas is now conducted through the closed flask, from the apparatus *a*, until the bubbles of gas issuing from the tube *g* are completely absorbed by the 20 per cent. caustic soda solution contained in the graduated tube. When complete absorption takes place the cock of the carbonic acid apparatus is closed, and the flask is heated very gradually. Decomposition now

ensues, with the evolution of nitric oxide. After the reaction is over, the contents of the flask are boiled down to a few cubic centimetres, and the last traces of nitric oxide are conducted into the measuring-tube by the aid of a stream of carbonic acid gas. For the

FIG. 4.

removal of nitroglycerin from dynamite, etc., W. Hampe uses Szombathy's apparatus for the estimation of fat in milk. This consists (Fig. 5) of an extraction tube *A*, with a connecting tube *b*, and an over-flow tube *c*; the top of this extraction tube is connected with a vertical

FIG. 5.

condenser *C*, and its lower end passes through the cork of a small flask *B*, containing about 25 c.c. of ether. The contents of the flask can be warmed in the water-bath *F* to from 70 to 75°. The dynamite is weighed in the

blown head of a thistle funnel D (fig. 6), containing a plug of glass-wool or asbestos; the funnel head is fastened to a ring of platinum wire, and it can be placed in a small stand made of platinum wire (fig. 7). Ten to 12 grms. of dynamite are weighed off, dried over sulphuric acid, placed in the extraction tube (in which the top of the funnel head will be at the level *a*), and treated with ether, until the solvent begins to run down by the syphon *c*. When the flask B is warmed, ether-vapour passes up through *b* into the condenser C, is condensed, drops upon the dynamite and gradually fills the tube A again, until the mark *a* is reached, when it runs back by the syphon *c* into the flask B. This circulation of the ether will take place 12 times in one hour; and within five hours 10 grms. of blasting gelatine can be completely extracted, while 10 grms. of gelatine dynamite can be entirely extracted in three hours. W. Reimert has introduced a modification of the warm process for the production of blasting materials, according to which he treats an intimate mixture of the materials by the direct action of steam: 75 parts of saltpetre, 13 parts of charcoal from white wood, 9 parts of sulphur, and 3 parts of flour or starch are made into a paste with 6 to 8 litres of water, brought into a steam apparatus, and there mixed with steam at a pressure of 2.5 to 3 atmospheres. The mixture is then run out, cooled, pressed into cartridges, and lastly dried. John Wallen, of Knittelfeld, has invented a powder, to which he has given the name of lederite. This compound consists of 45 parts of nitre, 15 parts of sulphur, 20 parts of red lead, 18 parts of leather cuttings (?), and 2 parts of picric acid. The poisonous vapours which would be evolved by this blasting powder constitute a formidable disadvantage, inseparable from its use. R. Punshon and R. R. Vizer, London, have patented a new process of blasting, in which they employ two glass cylinders, one filled with nitric acid and the other with picric acid, enclosed together in a case, so that, when the latter is placed in the bore-hole, the two compounds can by simple means be caused to mix and produce the required explosive. The principle of this invention is not new, the novelty consisting in its application to blasting purposes. Some experiments made at Saarbrücken with pressed powder (already widely used in England) tend to show that it is less dangerous to handle, less liable to miss discharge in wet coal, and that it is more effective than granulated powder, than which it is, according to recent experiments, 35 to 45 per cent. more powerful.—E. G. C.

## XXII.—GENERAL ANALYTICAL CHEMISTRY.

*Analysis of Vegetable Substances.* E. Reichert. Arch. Pharm. 222, 415.

THE author recommends the following method of procedure:—(1) determination of the ash; (2) determination of the protein substances—viz., by determination of the amount of nitrogen by Will-Varentrap's method and multiplication of the result by 6.25; (3) examination of the substance dried at 100°. 1 or 2 grm. are extracted with ether, and the dissolved portion reckoned as fat; the insoluble residue is extracted with 10 to 20 times its quantity of alcohol, and the soluble portion estimated as sugar; the insoluble residue is then treated with water, and the gum extracted and determined. The residue insoluble in ether, alcohol, and water, is boiled with 20 to 30 cc. of 5 per cent. sulphuric acid for an hour or more, while connected with a reversed condenser, filtered, and the residue boiled with 5 per cent. solution of caustic soda; the undissolved cellulose is washed, dried at 100° and weighed. The united acid and alkaline filtrates are united, strongly acidified, and boiled one or two hours and tested with Fehling's solution. The residues from the alcoholic and ethereal solutions require further examination.—H. B.

*The Determination of Manganese and Phosphorus in Iron, Steel, etc.* M. Troilius. Berg-u-Hüttenm. Zeit., 1884, 284.

THE fullest details are given for the separation of the manganese as dioxide, by boiling the strong nitric acid

solution with potassium chlorate. The chlorate must be added gradually and the solution repeatedly boiled, in order to get a complete separation. Phosphorus is determined by the ammonium molybdate method, which is also most fully detailed.—H. B.

*An Indicator for Use in Alkalimetry and Acidimetry.* A. Gawalowski. Biedermann's Cent-Blatt. Agrik. Chem. 1884, 4, 286.

THE author employs a mixture of alcoholic solutions of phenolphthalein and dimethyl aniline orange or methylorange. The mixture is lemon-yellow when quite neutral, and, on the addition of a drop of acid or alkali, is within from four to five seconds coloured rose-red or deep red, respectively.—E. G. C.

*On the Estimation of Silicon in Iron and Steel.* Thos. Turner. Chem. Soc. Journ. July, 1884.

IN the course of an investigation on the influence of silicon in iron and steel, the author had occasion to examine the various methods proposed for its estimation, and also for its separation from the slag present in the metal.

*Estimation of Total Silicon.*—I. The ordinary method of treating the finely divided metal with strong hydrochloric acid, evaporating to dryness, extracting with hydrochloric acid, washing, drying, and igniting the residue, gives rapid and tolerably accurate results with metal containing not more than 2.5% of silicon. The presence of manganese has no effect upon the results. This method has also the disadvantage of yielding a very bulky residue, from which it is difficult to burn the graphite. II. A method recommended in some textbooks, of treatment with hot strong hydrochloric acid, and filtering without previous evaporation, is not to be relied upon. III. Fusion of the silicious residue obtained by evaporating the hydrochloric acid solution and further separation with hydrochloric acid, gives perfectly reliable results, but the method is somewhat troublesome. IV. A fairly accurate method with moderate amounts of silicon, though giving somewhat high results with larger amounts, consists in treating the finely divided metal with hot aqua regia, evaporating to dryness, washing, filtering, drying and igniting. It has the advantage of yielding a residue from which the graphite is easily burned away. V. Drown's process (*Chem. News*, 42, 331) consists in treating the metal (not necessarily finely divided) with nitric acid, sp. gr. 1.2, and when the action has ceased, adding a small quantity of strong sulphuric acid. The solution is evaporated until it solidifies, when water is added and the liquid heated and filtered. The silica thus obtained is snow-white and granular. The method, which is neat and rapid, is not however applicable with large percentages of silicon and manganese.

*Separation of Slag.*—For this purpose the author recommends a modified form of the chlorine process. "The iron or steel, in large or small fragments, is placed in a porcelain boat and is burned in a stream of dry chlorine free from air. The excess of gas passing through the combustion tube is washed by passing through water contained in a weighed Varentrap's bulb. When the combustion is completed, as indicated by the entire absence of red vapours near the boat, the current is maintained for five to ten minutes, and the solution afterwards evaporated to dryness. The residue is extracted with hydrochloric acid to remove any iron, etc., sometimes carried over, then filtered, washed and ignited. The bulb is also weighed, after being carefully dried at 100°. These two weighings together furnish the whole of the unoxidised silicon originally present in the iron. The residue left behind in the boat contains carbon and slag, and also part of the manganese, a little iron as chloride, etc. It may be most conveniently transferred to a test-tube, boiled with a little dilute hydrochloric acid, filtered, dried and ignited. It is necessary to estimate the silica present in the residue, by fusion in the ordinary way, before any trustworthy opinion can be formed as to the amount of slag present. When this is done, the results

obtained by adding together the total silica found agree with those got by any other trustworthy method." In conclusion, the author sums up as follows:—"1. That methods I., III., IV. and V. give fairly concordant results with steel and ordinary cast-iron, while of these four the method proposed by Brown has the advantages of most rapid action, least bulky residue, and most easily burned graphite. 2. That for silicon pig and silicon ferro-manganese, methods I., II. and V. are quite inapplicable, while III. and IV. give moderately accurate results; but all these methods are incapable of distinguishing between oxidised and unoxidised silicon. 3. That the chlorine process in the modified form above suggested, has the great advantage of distinguishing between the unoxidised silicon and slag, whilst it is rapid and fairly accurate with all classes of iron, and hence may help to supply a long-felt want of the iron and steel analyst."—E. J. B.

*The Analysis of Zinc Flue-Ash and Pyrites Residues by the Carbonate of Ammonia Process.* By B. Kosmann. Chem. Zeit. viii. 61, 1991.

UNDER the common head of Zinc Flue-Ash come (1) the grey "Poussière" from the zinc distillation; (2) the flue dust from the chambers of the zinc distilling furnaces, fitted with Kleiman's receivers; (3) the zinc dust of iron blast furnaces. The author treats the above products with a solution of neutral carbonate of ammonia, which should be prepared by dissolving 230grm. of commercial carbonate in 180cc. caustic ammonia of 0.92 sp. gr., and diluting to one litre (H. Rose). By this solution all metallic zinc, oxide, and basic sulphate are dissolved, while cadmium and lead oxide, lead sulphate, and lime sulphate are decomposed and converted into insoluble carbonates. Iron and manganese when present as protoxides are almost wholly dissolved. Ferric oxide is also attacked. A small quantity of cadmium oxide in *statu nascendi* is also dissolved. The substance is first heated with a small quantity of water to 50° C. to 60° C., digested with the above solution and then filtered; the residue is washed with hot water (to which some of the solvent has been added) until no opalescence is produced with pure water. Should iron or manganese be present in the solution, it is oxidised with bromine, and the precipitate filtered with the original residue. The filtrate is then diluted and boiled until the excess of ammonia is driven off; it is then filtered, and the carbonate of zinc is ignited and weighed as zinc oxide, or it can also be estimated volumetrically with sodium sulphide in the original solution, for which purpose it must be divided into two parts, one of which is reserved for the estimation of sulphuric and arsenic acids. The filtrate from the zinc precipitate is divided into two parts, in one of which, after acidifying, the arsenic is precipitated with H<sub>2</sub>S; in the other, also acidified, the sulphuric acid is estimated with barium chloride. The residue is dissolved in dilute acetic or hydrochloric acid, and filtered (residue silicate, coke, etc.). In the filtrate, lead, cadmium, iron, aluminium, manganese, lime, and magnesia are estimated in the usual way. The metallic portion of the ash is estimated by means of cupric sulphate, by which zinc and cadmium are dissolved, and copper precipitated. The operation is conducted as follows: To a solution of weighed copper sulphate, so much ash from a weighed portion until the colour disappears, the entire precipitation of the copper being verified by H<sub>2</sub>S.—F. T. S.

*A Process for Distinguishing Iron from Steel.* Chem. Zeit. viii. 56, 1008.

ACCORDING to D. Sévoz the metal to be examined should, after being washed, be placed in a solution of chromic acid, prepared by decomposing bichromate of potash in concentrated aqueous solution, with an excess of sulphuric acid; after immersion from a half to one minute the metal is taken out, washed, and dried. The soft steels and cast-iron show, after this treatment, a uniform ash-grey colouration. Hard steels become almost black, without

any metallic lustre. Puddled iron remains almost white, with a metallic lustre on those parts of the surface which have been filed, while the rest of the surface shows irregular black spots.—F. T. S.

## New Books.

TECHNISCH-CHEMISCHES JAHRBUCH, 1883-1884. Ein Bericht über die Fortschritte auf dem Gebiete der chemischen Technologie von Mitte 1883 bis Mitte 1884. Herausgegeben von Dr. RUDOLF BIEDERMANN. Sechster Jahrgang. Mit 279 in den Text gedruckten Illustrationen. Berlin: Verlag von Julius Springer, 1885. Preis, 12 Mark (or 12s.).

This work is a concise yet admirably arranged repertorium of statistics showing the advance of chemistry as applied to the arts and manufactures during the space of time above defined. It takes the form of an 8vo volume bound in cloth, gilt, with table of contents, followed by one of statistics of the chemical industries in Germany, and another bearing upon the laws and regulations of transit, carriage of goods and chemicals, the laws of patent right, etc., in Germany. The work contains 481 pages of subject-matter, 33 pages of references to new books published in the period above mentioned, relating to physics, chemistry, chemical technology, mineralogy and geology, and miscellaneous branches, also alphabetical indexes (*a*) of names of authors, (*b*) of subject-matter. The general arrangement and mode of treatment of the subject is gathered from the contents, headed as follows: Chapters I. to VII. Metallurgy; VIII. Chlorine and Bleaching Powder, Hydrochloric Acid, Bromine; IX. Sulphur and Sulphurous Acid, Sulphuric Acid; X. Common Salt and the Soda Manufacture; XI. Potassium Compounds; XII. Ammonia; XIII. Alkaline Earths; XIV. Alum; XV. Glass; XVI. Earthenware; XVII. Lime and Cements; XVIII. Artificial Stone; XIX. Explosives; XX. Illuminants; XXI. Fuel and Heating; XXII. Sugar; XXIII. Starch and Starch-sugar; XXIV. Wine; XXV. Beer; XXVI. Spirits; XXVII. Fats, Resins, Oils and Soaps; XXIX. Foods; XXX. Manures; XXXI. Tanning; XXXII. Glue; XXXIII. Organic Acids; XXXIV. Alkaloids; XXXV. Textiles, Cellulose; XXXVI. Colouring Matters; XXXVII. Paper; XXXVIII. Photography; XXXIX. Apparatus; XL. New Books (Bucherschau).

FRESENIUS' QUANTITATIVE ANALYSIS, Vol. II. Translated by CHAS. E. GROVES, F.R.S. Part I. Price 2s. 6d.

This work, appearing in parts and bound in pamphlet form, 8vo size, is a translation of the German edition at present in course of issue from the pen of Prof. Fresenius of Wiesbaden, which has reached, so far, Part VI. (Lieferung. 6). Mr. Groves has most conveniently arranged the issue of his parts, and the numbering of them, in such wise that they coincide with the German arrangement exactly, so that a faithful reproduction of the work of the veteran German analyst is thus assured. The present issue, or Part I., is devoted to the subject of Organic Analysis, contains ninety-six pages of subject-matter arranged exactly as in the German edition, and interspersed in the text are seventy-five engravings, representing the apparatus used and its arrangement in detail and system for the analytical and other operations for which it is required.

# Monthly Patent List.

## ENGLISH APPLICATIONS.

1885.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

- 791 A. Althusen, London. Improvements in the construction and working of furnaces or apparatus for burning pyrites and for analogous purposes. January 20
- 815 J. Robertsshaw and J. T. Turner, Manchester. Improvements in disinfecting apparatus. January 21
- 966 H. Kenyon, Manchester. Improvements in ovens or retorts, and connected apparatus for use in the distillation and decomposition of coal shale and other matters. January 23
- 975 G. S. Hazlehurst, London. Improvements in and apparatus for evaporating and concentrating liquids and depositing their contents. January 23
- 980 S. B. Darwin, Westminster. Improvements in adjustable dip-pipes and their appendages, used in the manufacture of gas. Complete specification. January 23
- 1001 J. H. Selwin, London. Improvements in liquid fuel furnaces and their appliances. January 23
- 1038 C. Bramall, London. An improved compound or lining to be used in lining or constructing smelting and other furnaces. Complete specification. January 23
- 1162 J. G. Hawkins, Westminster. Improvements in gas retort-charging apparatus. January 27
- 1170 W. Ball and J. Lenoxx, London. Improvements in machinery or apparatus for pressing or moulding pulverised or other materials into bricks, blocks, or cakes. Complete specification. January 27
- 1176 H. D. Cunningham, London. Apparatus for cooling cement, flour, and other substances. January 27
- 1221 W. Kent, Jersey City, United States. Improvements in furnaces. Complete specification. January 28
- 1330 T. Jefferies, London. New or improved machinery or apparatus for charging gas retorts. January 30
- 1375 T. Vaughan Hughes, London, and F. W. Harbord, Bilston, Staffordshire. Improvements in the manufacture of basic plug bottoms and bricks for the interior of Bessemer converters. January 30
- 1453 T. W. B. Mumford and R. Meodie, London. Improvements in apparatus for separating substances of different specific gravities. February 2
- 1510 G. Fletcher and W. F. Abell, London. Improvements in centrifugal machines for drying sugar and other crystalline or granular substances. February 4
- 1511 G. Fletcher, London. Improvements in centrifugal machines. February 4
- 1615 P. Penn-Gaskell, London. Apparatus for treating fish for producing oil and manure. February 5
- 1633 G. W. Wilkinson, Birmingham. Improvements in gas kilns for burning glass, china, pottery-ware, and other such like articles. February 5
- 1667 T. C. Lewis, London. Improved apparatus for generating heat in steam-boiler furnaces. Communicated by F. Yates, Germany. February 6
- 1767 A. Behr, London. Improved apparatus and process for obtaining cellulose and glucose from wood and other vegetable matter. February 9
- 1837 W. Davidson, London. Improvements in kilns for drying granular substances. February 10
- 1891 J. Richmond and B. Birtwistle, London. Improvements in furnaces for treating tannin and other refuse. February 11
- 1912 W. Mather, London. Apparatus for steaming in the bleaching of fibres, fabrics, and yarns. Complete specification. February 11
- 1955 R. Morris and J. Wood, London. Improvements in apparatus for grinding or reducing quartz and other hard or brittle substances. February 12
- 1956 J. Humphrys, London. Improvements in apparatus for the precipitation of solid matter held in suspension in liquids. February 12
- 1975 J. Watson and J. L. Spoor, London. Improvements in and connected with kilns employed in the manufacture or burning of Portland cement, and other analogous operations. February 12
- 1977 H. J. Hadden, Westminster. Apparatus for drying in vacuo. Communicated by E. Passburg, Russia. Complete specification. February 12
- 1982 W. L. Wise, London. Improvements in apparatus for the decarbonation of carbonate of barium and carbonate of strontium. Communicated by R. Radot, France. February 12
- 2002 A. Whitwell, London. An improved agitator and boiler for bleaching and finishing purposes. February 13
- 2009 A. Whowell, London. Improvements in or applicable to machinery known as drying tins. February 13
- 2033 C. Price, London. Improvements in kilns for burning and drying bricks and other articles. February 13
- 2042 G. G. Arvedson, London. Improvements in casting ladles for casting iron, steel, and other metals. Complete specification. February 14
- 2126 W. H. Luther, London. Improvements in vessels or baths for galvanising, tinning, or coating iron or other metal. February 15
- 2150 W. P. Thompson, Liverpool. Improvements in presses for the extraction of oil or other liquids from substances containing them. Communicated by F. Jourdan. February 17

### II.—FUEL, GAS, AND LIGHT.

- 2169 A. Dempster, London. Improvements in apparatus for purifying coal gas. Complete specification. February 17
- 2188 J. C. Thompson, London. Improvements in screw presses for extracting oils, and for other purposes. February 17
- 2221 T. L. Ellis, Glasgow. Improvements in reverberatory furnaces. Complete specification. February 18
- 2289 A. Wilson, London. Improvements in crucible furnaces. February 19
- 802 A. J. Boulton, London. Improvements in the manufacture of illuminating gas from hydrocarbon or other oils, and in apparatus therefor. Communicated by J. Hanlon, United States. Complete specification. January 20
- 805 A. J. Boulton, London. Improvements in the manufacture of gas for illuminating or other purposes, and in apparatus therefor. Communicated by J. Hanlon, United States. Complete specification. January 20
- 815 H. J. Hadden, London. Improvements in apparatus for and the method of utilising heat developed by combustion. Communicated by W. M. Jackson, United States. Complete specification. January 20
- 915 F. J. Jones, Redwely, Worcestershire. Improvements in the production of combustible gases from finely pulverised coal, peat, wood-sawdust, or other material. Complete specification. January 20
- 920 T. Wright, Halifax. Improvements in the means or method of utilising the waste heat and gases arising from steam-boiler furnaces. January 22
- 947 H. Kenyon, Manchester. Improvements in the distillation and decomposition of coal, shale, and other matters, to obtain illuminating gas and other products. January 23
- 1026 J. Hanson, Bingley, Yorkshire. Improvements in the method of and apparatus for purifying coal gas. January 21
- 1081 J. Reid, Birmingham. The reactivation of hydrate of lime after it has been used once for the purification of gas. January 23
- 1100 J. Watson, London. Improvements in the application of gas fuel to boilers for heating purposes. January 31
- 1368 R. Punshon and S. H. Beckles, London. Improvements in the chemical treatment of hydro-carbons. February 12
- 1402 G. Gruber, London. Kindling stuff (Phonix composition). Complete specification. February 14
- 2190 A. Gutensohn, London. Improvements in obtaining gas from hydrocarbons. February 17

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, ETC.

- 967 H. Kenyon, Manchester. Improvements in the distillation and decomposition of coal, shale, and other matters, to obtain illuminating gas and other products. January 23

### IV.—COLOURING MATTERS AND DYES.

- 1553 H. E. Newton, London. An improved process for the production of chlorinated dimethylparaphenylenediamines and the conversion of the same into blue colouring matters containing sulphur. Communicated by R. Mohlau, Germany. February 4
- 1643 I. Levinstein, Manchester. Improvements in the manufacture of colouring matters suitable for dyeing and printing. February 6
- 2206 H. J. Hadden, Westminster. Process or processes for the production of soluble combinations of certain azo compounds with bisulphites, and for utilising the same in dyeing and printing. Communicated by Dr. F. Frank and the Farbenfabriken Vormals Bayer & Co., Prussia. Complete specification. February 17

### V.—TEXTILES, COTTON, WOOL, SILK, ETC.

- 1232 W. L. Wise, London. Improvements in means for rendering fabrics and other substances unflammable, obnoxious to vermin, resistant to putrefaction, to the reception of morbid or diseased matter, and to the growth of spores, fungi, bacteria, etc. Communicated by J. F. Notz and F. Konrad, Saxony. January 28

### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

- 1127 J. Midgley, Shipley, Yorkshire. Dyeing yarns by a specially prepared apparatus. January 27

### VII.—ACIDS, ALKALIS, AND SALTS.

- 800 H. W. Deacon, F. Hurter, and W. Elnore, London. Improvements in the treatment of sulphides in alkaline solutions by electrolysis. January 20
- 1013 F. M. Lyte, London. Improvements in the manufacture of aluminate of soda. January 23
- 1659 C. W. Watts, Birmingham, and C. F. Claus, Wimbeldon, Surrey. Improvements in the treatment of solutions of sulphur granules in order to obtain useful products therefrom. February 6
- 1723 W. H. Higgin, Little Lever, Lancashire. Improvements in the manufacture of bichromate of soda. February 7

1868 W. R. Lake, London. The protection of nitrate of ammonia against deliquescence. Communicated by R. S. Penman, United States. Complete specification. Feb. 10

1869 E. K. Musprat and G. Eschlinmann, London. Improvements in the manufacture of magnesium chloride. February 11

1867 E. W. Parnell and J. Simpson, Liverpool. Improvements in the recovery of ammonia in the manufacture of carbonate of soda by the ammonia process with production of sulphurated hydrogen. February 12

1871 J. H. Johnson, London. Improvements in the manufacture of caustic baryta. Communicated by H. Kessler, France. February 12

1878 A. McDonald, Perth. Improvements in the methods of obtaining hydrochloric acid in the manufacture of soda from sodium chloride by the ammonia process. Complete specification. February 11

1893 F. Harbe, London. An improved method of solidification of phosphoric acid by a mineral or a vegetable substance, being porous bodies. February 17

2283 G. A. Jarvis, London. Extracting potash from felspar or felsstone rocks. February 15

### VIII.—GLASS, POTTERY, AND EARTHEN-WARE.

1118 J. G. Muller, London. Improvements in the manufacture of tiles and other objects in imitation of majolica ware. February 2

### IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

833 W. R. Lake, London. An improved process and apparatus for treating wood. Communicated by the presentation of railway sleepers. Communicated by E. Z. Collings and C. F. Pike, United States. Complete specification. January 20

881 B. J. B. Mills, London. A process for the agglomeration or consolidation of materials, and for the hardening of stone, cements, and other materials. Communicated by C. Labore, France. January 21

887 A. J. Boulle, London. Improvements in the manufacture of tiles and other articles from plastic materials, and in apparatus therefor. Communicated by F. C. A. Meier, Germany. Complete specification. January 21

910 J. A. Graham, Liverpool. Improvements in drying bricks and other articles, and in plant or apparatus therefor. January 22

1332 H. C. de Berengier, London. Improvements in plaster ceilings and walls. January 31

1778 J. Tomlinson, London. Improvements in the manufacture of plaster or cement. February 9

2095 J. Boulton, London. Improvements in fireproof floors. February 14

2153 L. A. Brode and T. T. Rankin, Glasgow. The manufacture of an improved hydraulic cement. February 17

2161 H. Fajla, London. Improvements in the mode and apparatus for treating slurry or slip in the manufacture of Portland cement and bricks. Complete specification. February 17

### X.—METALLURGY, MINING, ETC.

870 J. H. Johnson, London. Improvements in the manufacture of metallic alloys. Communicated by the Societe Anonyme "Le Ferro-Nickel," France. January 21

1020 Peter Kirk, Manchester. Improvements in the production of rolled metal sleepers for permanent way. Jan. 21

1021 E. von Puttner, Liverpool. Improvements in the extraction of magnesium. Complete specification. January 21

1036 H. Hall, London. Improvements in the method of coating metal plates with tin and other metal. January 24

1161 P. Jensen, London. An electrolytic process for obtaining, separating, and cleansing certain metals and alloys, and removing coatings thereof from other metals. Communicated by Dr. O. Kersten, Germany. January 27

1259 E. Glatzel, Hildach. A process for making use of zinc refuse. January 29

1266 J. Head, London. A mode of dividing steel blooms and apparatus for carrying the same into effect. January 29

1268 C. A. Faure, London. Improvements in the manufacture of sodium and potassium. January 29

1238 L. Q. Brin and A. Brin, London. Improvements in the manufacture of ferro-nickel, an alloy of nickel and iron; applicable also to the refining of nickel. January 30

1261 E. Melan and N. A. J. Contarini, London. Improvements in the mode of and apparatus for the manufacture of steel from cast iron. January 30

1269 P. Kirk, Manchester. Improvements in the production of rolled metal sleepers for permanent way. January 31

1271 H. Garner, Birmingham. Improvements in segmental metallic cores to be used in the casting of metals. January 31

1573 G. Lowe and H. Levett, Birmingham. An improved alloy for mercurial gilding. February 5

1866 G. Rowell, London. Improvements in the manufacture of iron and steel. February 10

1917 W. R. Lake, London. An improved process for annealing copper or its alloys. Communicated by W. Wallace, United States. Complete specification. February 11

1931 R. Schliwa, L. Gildemeister, and R. Feldtmann, Glasgow.

Improvements in treating iron in the Bessemer converter or similar apparatus, for the elimination of silicon, phosphorus, sulphur, and for the formation of slags containing phosphoric acid soluble in water. Complete specification. Feb. 12

2025 L. Q. Brin and A. Brin, London. Improvements in separating metals from their ores, refining metals, and making alloys of metals, and analogous operations. February 13

2161 R. Hadfield, London. Improvements in the manufacture and treatment of tool steel. February 17

### XI.—FATS, OILS, AND SOAP MANUFACTURE.

1080 W. G. Little, Rotham, Yorkshire. Improvements in the manufacture of soap and disinfectants. January 26

1191 W. P. Thompson, Liverpool. Improvements in the process of pressing oil seeds or other oleaginous matters, or matters containing other liquids for the purpose of extracting such oil or liquids therefrom, and in apparatus therefor. Communicated by E. Torelli, Italy. January 28

1357 J. Dinning, London. A detergent composition for removing old paint, varnish, or paper and rust, or other impurities from wood, plaster, or other surfaces. January 30

1339 W. G. Hadley, London. Improvements in the preparation of oils for medicinal purposes. Complete specification. January 31

2100 H. H. Lake, London. An improved method or process of purifying fat and oil. Communicated by J. P. A. Larson, Sweden. Complete specification. February 11

2210 C. T. Kingzett, London. Improvements in the production of compounds which may be usefully employed for the destruction of insects on plants and animals; also as lubricants; also for sheep dipping; and generally as soaps or detergents for washing, cleansing, and purifying purposes. February 17

### XII.—PAINTS, VARNISHES, AND RESINS.

966 J. C. W. Stanley, London. Improvements in the manufacture of pigments or colours. January 23

1103 H. Rees, Wandsworth, Surrey. A method of making crystallised colours, and for receptacles to hold the same ready for use. January 26

1001 T. J. Pearce and M. W. Beardsley, London. Improvements in rendering substances impermeable to air and liquids; in imparting to wood, metal, leather, and rubber, animal and vegetable fibre, and fabrics and products thereof, waterproof and weatherproof qualities, and the property of resisting acids and alkalis, in coating and covering electric wires and conductors to insulate them; in rendering submarine structures proof against rot and decay, and the attacks of marine animals; and in the production of a compound suitable for use as a paint, and a protective and preservative coating. February 5

2011 H. J. T. Ford, London. Preservative composition for the bottoms of iron ships and steam boats. February 13

2070 A. C. Bagot, Rugeley, Staffordshire. An improved composition for preventing rust on metals. February 11

### XIII.—TANNING, LEATHER, GLUE, AND SIZE.

2026 T. Macdonald and S. L. Evans, London. Improvements in the manufacture of leather. February 13

### XIV.—AGRICULTURE, MANURES, ETC.

1835 J. Ross, London. An improved method of treating scrap and old leather for the purpose of manufacturing manure. February 10

2282 G. A. Jarvis, London. Improvements in agricultural manures. February 19

### XV.—SUGAR, STARCH, GUM, ETC.

865 A. G. Wass, London. The improved utilisation of sugar cane. January 21

1400 W. Smartt, London. Improvements in the preparation of vulcanised India rubber and the several analogous substances for attaching to boot soles and other surfaces. Jan. 23

1356 C. & J. Lyle, London. Improvements in the manufacture of lump sugar. January 30

1413 H. J. Hadden, Westminster. Improvements in the process of extracting saccharine matters. Communicated by K. Trobach, Germany. February 2

1872 G. A. Day, Holborn, London. Improvements in means and apparatus for bleaching sugar. Communicated by E. O. Foster, United States. Complete specification. February 12

### XVI.—BREWING, WINES, SPIRITS, ETC.

1022 J. Deane, junr., Cheshunt, Hertfordshire. Improvements in preparing clarified grain for use in brewing. January 21

2078 W. H. Beck, London. A new or improved artificial froth or head for use in the fermentation of fermentable liquids. (Mons. Marcus, France.) February 11

2248 W. R. Lake, London. Improvements relating to the preparation of food for animals from the refuse of breweries or of starch and glucose factories and apparatus therefor. Communicated by F. W. Wiesebroek, United States. Complete specification. February 17

## XVII.—FOOD PRESERVING, MEATS, Etc.

- 1531 C. Russell, Tooting, Surrey. Preserving meat. Communicated by A. Losasso, Calcutta. Complete specification. February 1.  
 1550 P. M. Justice, London. Improved process of treating meat, apparatus therefor, and product derived therefrom. Communicated by G. Holgate, United States. February 1.

## XVIII.—SANITARY CHEMISTRY, DISINFECTANTS, Etc.

- 777 W. P. Thompson, Liverpool. Process for sterilising liquids and apparatus therefor. Communicated by H. Danvers and C. Beretta, France. January 20.  
 830 J. Hanson, London. Improvements in softening water. January 20.  
 900 F. M. Lyte, London. Improvements in purifying and deodorising sewage and other foul waters, and obtaining a useful product therefrom. January 21.  
 908 G. H. Ellis, Exeter. A new or improved process for the manufacture of a filtering, deodorising, and decolourising substance or medium from carbonaceous or lignite clay. January 22.  
 111 W. F. Gedge, London. A process of purifying water for domestic and industrial purposes and apparatus therefor. Communicated by Fedor Wolff and Co., Germany. Jan. 27.  
 1580 A. B. Lorenz, Beverley, Yorkshire. Preventing water in reservoirs and pipes becoming stagnant and creating gases or becoming otherwise prejudicial to health. February 3.  
 1718 A. J. Shilton, Birmingham. A new disinfectant. Feb. 9.  
 1766 P. Smith and J. T. Smith, Anclney. An improved process and apparatus for evaporating sea water, specially applicable for supplying marine boilers. February 9.  
 2011 J. Horne and S. Hollyman, London. Improved means and appliances for treating foul and noxious gases and vapours for the ventilation of sewers, drains, houses, rooms, and other places. February 13.  
 2167 M. Maloin, London. An improved method of exhausting sewer gas from sewers or drains, and consuming or deodorising and disposing of the same. February 17.  
 2173 T. Kay, Stockport. A method of and apparatus for making sea water drinkable. February 17.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

- 1006 C. A. Day, London. Improvements in the manufacture of vanilline. Communicated by A. Scheidel, Italy. January 23.

## XXI.—EXPLOSIVES, MATCHES, Etc.

- 1527 M. Ingram, Manchester. Improvements in railway and other signals for use during fog, snow-storms, or darkness. February 1.  
 2139 A. Pavier, France. New explosive compounds. Complete specification. February 16.

ENGLISH PATENTS PUBLISHED.  
APPLIED FOR DURING 1881.

## I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

- 2368 H. Hargreaves, W. Beckett, and W. Cliffe. Constructing kilns and ovens for burning limestone and bricks, and other like materials. 6d.  
 2829 G. Patchett, J. Dixon, and R. Tensdale. Means or apparatus for the manufacture of bricks, paving blocks, or the like, from the slag or scoria of blast furnaces. 6d.  
 1298 A. J. Boulton. Communicated by the Schlesische Kohlen und Cokeswerke, Gottesberg. Improvements in regenerative coke furnaces. 2d.  
 1650 H. J. Haddan. Communicated by O. Obermaier, Lambrecht, Bavaria. Apparatus for treating textile materials with liquids or gases. 6d.  
 1879 J. Watson. Improved apparatus to be used in the manufacture or preparation of cement. 6d.  
 1902 W. R. Lake. Communicated by L. Fouque. Apparatus for drying and superheating steam, and for similar purposes. 6d.  
 3267 R. H. Hepburn. Furnaces, and apparatus for supplying steam and air thereto in order to cause more perfect combustion of fuel. 6d.  
 3276 J. Monson. Apparatus for admitting air to steam-boiler and other furnaces for the consumption of the gases arising therein, and the prevention of smoke. 8d.  
 3288 E. H. Waldenstrom and W. Sumner. Preventing corrosion of metal tubes. 2d.

\*Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lusk, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 5s. ....	5d.
Above 5s. and not exceeding 1s. 6d. ....	5d.
" 1s. 6d. " " " 2s. 6d. ....	10d.
" 2s. 6d. " " " 3s. 6d. ....	2d.

- 6001 D. Burns. Composition for covering boilers or other vessels or bodies, so as to prevent them losing or gaining heat. 2d.  
 6383 A. Munzinger. Drying apparatus for treating pulp and other substances. 8d.  
 7783 C. Price. Air blast or exhaust kiln, with one or more chambers for burning bricks, pipes, tiles, etc. 2d.  
 9301 W. Weldon. Communicated by A. R. Peckney et Cie. Furnaces for heating solid substances out of contact with the products of combustion of the fuel employed. 6d.  
 11539 W. P. Thompson. Communicated by J. F. Haurahan. Arrangement and construction of refrigerating chambers or buildings. 6d.  
 1588 H. H. Lake. Communicated by C. W. Floodgirt. Boilers for use in treating wood or other fibrous materials with acids. 1d.  
 15417 S. Adams. Self-sealing mouthpieces and lids for retorts, stills and generators, for the production of gas from coal and other substances, also for distillation of liquids, etc. 1d.  
 16018 T. Gillespie. Improvement in blast smelting furnaces. 2d.

## II.—FUEL, GAS, AND LIGHT.

- 1698 W. H. Spence. Communicated by F. W. C. Waldeck. The Hague. Method of utilising the waste residues of fuel. 1d.  
 1855 W. P. Wilson. Manufacture of gas for illuminating purposes, and apparatus or means to be employed therein. 6d.  
 3575 H. Springmann. Communicated by Dr. Hipp and Dr. Grunberg. Utilising the waste materials employed for the purification of lighting gas. 2d.  
 5871 F. C. Hills. Treatment of gas-liquor for use in the purification of coal gas. 6d.  
 15719 H. H. Lake. Communicated by R. H. Smith. Method or process of and apparatus for recovering paraffin, stearin, or similar waxlike substances from petroleum or other oil. 6d.  
 15196 A. McDougall. Manufacture of ammoniacal salt, and purification of gas. 2d.  
 16750 H. Greco. Means for effecting tight closure of gas retorts. 1d.

## III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

- 5033 R. Irvine. Distillation of shale coal or the like, for obtaining solid paraffin therefrom. 1d.

## IV.—COLOURING MATTERS AND DYES.

- 2666 J. H. Loder. Manufacture of alcohol and alcoholic solutions of colouring matters. 1d.  
 1850 J. H. Johnson. Communicated by H. Caro, Ludwigshafen, Germany. Preparation of halogen derivatives of tetramethyldiamidobenzophenone and analogous ketone bases. 1d.  
 5021 F. Wirth. Communicated by E. Erlenmeyer, Frankfurt-on-Main. Improvements in colouring matters. 1d.  
 5038 J. H. Johnson. Communicated by H. Caro, Ludwigshafen, Germany. Preparation of colouring matters suitable for dyeing and printing from halogen derivatives of tetramethyldiamidobenzophenone and analogous ketone bases. 6d.  
 5158 F. Machenhauer. Manufacture of yellow colouring matters. 1d.  
 5711 J. H. Johnson. Communicated by the Badische Anilin und Soda-Fabrik. Preparation of yellow, orange, and orange-brown colouring matters suitable for dyeing and printing from tetramethyldiamidobenzophenone and analogous ketone bases or their halogen derivatives. 1d.  
 11037 F. W. Renaut. Communicated by C. Collin and L. Benoist. Indigo vats, and vats for dyeing with noir-bien or with mixtures of noir-bien and indigo. 1d.

## V.—TEXTILES, COTTON, WOOL, SILK, Etc.

- 5317 A. W. L. Reddie. Communicated by Dillies et Cie., Roubaix, France. Treatment of vegetable and other tissues or fibres for the purpose of preserving or waterproofing the same. 1d.

## VII.—ACIDS, ALKALIS, AND SALTS.

- 2086 M. Finch, W. Willoughby, J. Willoughby, and S. Willoughby. Method of and apparatus for manufacturing sulphuric acid. 6d.  
 2673 C. Wigg and J. W. Pratt. Manufacture of soda and chlorine. 1d.  
 1195 C. S. Gorman. Manufacture of bichromate of soda. 2d.  
 1841 W. J. A. Donald. Manufacture of chromates and bichromates. 1d.  
 1947 S. G. Thomas. Manufacture of phosphoric salts. 2d.  
 3130 S. G. Thomas. Manufacture of chromic compounds. 2d.  
 5520 W. A. Meadows. Manufacture of sulphate of ammonia. 1d.  
 5948 W. J. A. Donald. Manufacture of chromates and bichromates. 1d.  
 6176 E. Paekard, jun. Obtaining certain solutions containing free phosphoric acid. 1d.

- 6750 E. Packard, jun. Manufacturing very pure and rich superphosphates of lime. 1d  
 6751 E. Packard, jun. Obtaining from native or other phosphate of lime products rich in phosphoric acid and of a high degree of purity. 1d  
 6752 E. Packard, jun. Obtaining from native or other phosphate of lime products rich in phosphoric acid. 1d  
 7036 Sir F. C. Knowles, Lovell Hill. Treating sulphides and oxides of metals and obtaining products therefrom. 2d

#### IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

- 7304 D. H. Brandon. Communicated by D. A. Brown and C. F. Brigham. Asbestos compound for use as boards or sheathing for roofings, car brakes, and for building and other purposes. 1d  
 1087 J. Farthing and J. H. Lorrimer. Manufacture of artificial asphaltic. 2d  
 1096 J. and H. Masgrave-Masgrave. Fire-proof ceilings and walls for houses and other buildings. 2d  
 1251 E. Brady. Composition of matter as a substitute for wood, stone, and iron, consisting of clay and vegetable pulp and coal ashes, or either of them, combined and mingled with felspar and caustic soda, etc. 2d

#### X.—METALLURGY, MINING, Etc.

- 2263 J. D. Thomas, T. W. Evans, and J. Gravel. Manufacture of tin and ternite plates. 6d  
 2249 J. Lewthwaite. Improvements in metals and alloys or mixtures of the same. 1d  
 4865 R. J. Atcherley. Method and apparatus for the amalgamation of free gold. 6d  
 5345 C. Billington and J. Newton. Alloying manganese iron and tin or lead and manganese iron, tin, and lead. 2d  
 6172 G. A. Dick. Manufacture of metallic alloys. 4d  
 8553 S. H. Smythe. Treatment and production of iron, and apparatus employed therefor. 6d  
 9469 T. Slater. Manufacture of chromium alloys. 1d  
 12011 H. Herenschmidt. Extraction of cobalt, nickel, and manganese from their ores, and of nickel from its ores, when such ores are found in a similar condition to those of New Caledonia. 2d  
 13560 A. Gatenshon. Process for coating iron or other metals with tin, lead, or ternite. 1d  
 15557 E. Probert. Process of working auriferous and argentiferous arsenides and sulphides of iron, copper, or other similar substances by litharge or lead. 1d  
 15226 W. Pennam. Treating cast steel for effecting the annealing thereof. 2d

#### XI.—FATS, OILS, AND SOAP MANUFACTURE.

- 579 M. Williams. Manufacture and preparation of drying oils. 1d

#### XII.—PAINTS, VARNISHES, AND RESINS.

- 2396 O. Wolff. Communicated by A. T. Bergh, Dresden. Manufacturing weather-proof oil colours or paints. 2d  
 4115 G. W. von Nawrocki. Communicated by P. Bottiger, Lodz, Russia. Method of manufacturing new pigments. 1d

#### XIII.—TANNING, LEATHER, GLUE, AND SIZE.

- 3378 W. Guest. Improvements in the treatment of leather. 2d

#### XIV.—BREWING, WINES, SPIRITS, Etc.

- 2330 H. J. Hadden, London. Communicated by C. Coster, Brussels. Process for the manufacture of alcohol. 1d  
 4182 E. T. Pemberton. Brewing or producing ale and porter. 1d  
 8896 F. W. Thompson. Manufacture of invert sugar for brewing and other purposes. 2d

#### XV.—FOOD PRESERVING, MEATS, Etc.

- 4133 G. T. Carter. Process for the manufacture of self-raising flour. 2d

#### XVIII.—SANITARY CHEMISTRY, DISINFECTANTS, Etc.

- 92 S. C. Deas. Purifying sewer gas and mephitic vapour. 6d  
 5175 J. Brown. Disinfecting litter, powder, and compounds. 2d  
 5117 J. B. Austin. Manufacture of carbolate of lime for disinfecting and deodorising purposes. 2d  
 8656 A. Irving. Effecting the complete purification of water contaminated by dissolved vegetable matter. 6d

#### XIX.—PAPER, PASTEBOARD, Etc.

- 4202 J. Fonlis. Methods or process of and apparatus for draining, concentrating, clarifying, and solidifying or consolidating substances and liquids, especially applicable for filtering paper-mill sludge and consolidating the substances contained therein. 6d

#### XXI.—EXPLOSIVES, MATCHES, Etc.

- 5382 H. E. Newton. Communicated by A. Nobel. Explosive compounds. 1d  
 5422 H. H. Lake. Communicated by F. H. Snyder. Explosive projectiles. 6d  
 5505 T. Allen. Manufacture of lucifer matches. 6d

# THE JOURNAL OF THE Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 3.—VOL. IV.

MARCH 30, 1885.

Non-Members 30/- per annum; Members  
21/- per Set; Single Copies 2 6.

## COUNCIL.

*President:* Dr. W. H. Perkin, F.R.S.

*Vice Presidents who have filled the Office of President:*

Sir H. E. Roscoe, Ph.D., F.R.S.  
Sir Frederick Abel, C.B., D.C.L., F.R.S.  
Walter Weldon, F.R.S.

*Vice-Presidents:*

Alexander M. Chance.	David Howard.
George E. Davis.	D. B. Hewitt, M.D.
Prof. James Dewar, F.R.S.	E. K. Muspratt.
James Duncan.	J. C. Stevenson, M.P.
David Gamble.	

*Ordinary Members of the Council:*

Eustace Carey.	John Pattinson.
Prof. Chas. Graham, D.Sc.	Thomas Kioyle.
Peter Griess, Ph.D., F.R.S.	John Spiller.
Ivan Leviustein.	Prof. W. A. Tilden, F.R.S.
H. Messel, Ph.D.	John Williams.
B. E. H. Newlands.	P. J. Worsley.

With the Chairmen and Secretaries of Local Sections.

*Honorary Treasurer:*

E. Rider Cook, East London Soapworks, Bow, E.

*Honorary Foreign Secretary:*

Ludwig Mond, 28, Park Crescent, Portland Place, W.

*General Secretary:*

Charles G. Cresswell, Palace Chambers, 9, Bridge Street,  
Westminster.

## THE JOURNAL.

*Publication Committee:*

*The President.*

Sir F. A. Abel, F.R.S.  
Joseph Bernays, M.I.C.E.  
Eustace Carey.  
W. Lant Carpenter.  
George E. Davis.  
Prof. Dewar, F.R.S.  
Chas. Ekin.  
Prof. Chas. Graham, D.Sc.  
Peter Griess, Ph.D., F.R.S.  
D. B. Hewitt, M.D.  
David Howard.  
Prof. A. K. Huntington.  
F. Hunter, Ph.D.  
E. W. T. Jones.

Ivan Leviustein.  
Raphael Meldola.  
Ludwig Mond.  
Chas. O'Neill.

## NOTICES.

The Executive Council of the Inventions Exhibition, having on the motion of Sir F. A. Abel, C.B., D.C.L., F.R.S., and Chairman of the Juries Commission, kindly allowed to members of the Society the privilege of season tickets at half price, these may be had upon application, accompanied by remittance of 10s. 6d., to the General Secretary at the Society's Office, Palace Chambers, Bridge St., Westminster, S.W.

Members are hereby informed that the Annual General Meeting (1885) will take place in London in or about the second week in July. Details and arrangements will be published in due course, and members will receive their tickets of membership, which, as heretofore, will form vouchers in visiting works and places of interest.

Authors of papers printed in the Journal are hereby notified of the fact that, in accordance with Bye-law 43, they are entitled to receive not more than 50 gratuitous copies of their papers. Authors should state on their manuscripts their desire to have free copies, adding the number wished for. Unless the contrary be specially desired, this being stated on the manuscript, the reprints of an author's paper will not include the report of any discussion that may have arisen after the reading of the paper.

Members are hereby advised that the Subscription for 1885 falls due at the beginning of the year, and should be paid as soon afterwards as possible. The Council has decided that after January 1st, 1885, the 29th Bye-law will be strictly enforced, so that Members whose subscriptions are more than four months in arrear, will not continue to receive the Society's Journal.

Inquiries having been made as to the transactions of the Newcastle Chemical Society, the Committee of the Newcastle Section have to state that a very few complete sets are remaining, and will be sold to members at £2 10s. per set. A number of separate volumes can also be had by members wishing to complete their sets, at 10s. per volume (generally three years' issue). Application for these should be made to the Local Secretary of the Newcastle Section.

## LIST OF MEMBERS ELECTED MARCH 23rd, 1885.

Dr. Powland J. Atcherley, 37, Ashchurch Grove, Starch Green, W., mining engineer.  
F. G. Blake, Mansfield Valley, Allegheny Co., Pa., U.S.A., Manager Lead Works.  
J. T. Board, Distillery, Cheese Lane, Bristol, distiller.  
Samuel Callard, Pontamman Chemical Works, Ammanford, Carmarthen.  
H. Hugham Clark, 2, Park Prospect, Queen Anne's Gate, S.W., manufacturer.  
Walter J. Cox, Rock House, Basford, Nottingham, dyer.  
St. John V. Day, C.E., 115, St. Vincent Street, Glasgow, patent agent.  
J. A. Deane, Oxalic Acid Manufactory, Morriston, Swansea, analyst.

D. C. Defries, 53, Redcliffe Square, South Kensington, gas engineer.  
C. F. Dobson, Lenton Road, The Park, Nottingham, lace dresser.  
C. F. Forshaw, 8, St. Andrews, Listerhills, Bradford, Yorks., dentist.

Jno. Eyfe, 7, West George Street, Glasgow, Director Young's Oil Company.

John Haxson, Fern Villa, Belle Vue, Wakefield, manufacturing chemist.

Booth Harris, jun., Clovelly House, Norwich Road, Forest Gate, E., soap maker.

Robert Hulton, Laboratory, 47, New Lawther Street, Whitehaven, analyst.

Frank H. H. Inghis, 21, Mining Lane, London, E.C., merchant.

A. Bowdler Hill, 101, Southwalk Lane, London, S.E., wholesale druggist.

Wm. Jennings, The Elms, Woolthorpe Rise, Sherwood, Nottingham, lace dresser.

S. G. Johnson, Pelham Crescent, The Park, Nottingham, town clerk.

A. P. Laurie, Nairne Lodge, Duddingstone, Edinburgh.

Leonard Lintley, Sherwood Street, Nottingham, lace dyer.

A. A. Magnien, 32, St. Mary at Hill, E.C., filter maker and chemist.

A. P. Matheson, 3, Lombard Street, London, E.C.

A. C. McCornqudale, Lowton Grange, Newton le Willows, Lancashire.

T. O. McMillan, 4, Ardgowan Terrace, Glasgow, chemist.

C. C. Melliss, M.C.E., 232, Gresham House, Old Broad Street, E.C.

Lock Moore, Newcastle Chambers, Nottingham, patent agent.

W. H. North, 4, Whetley Grove, Manningham, Bradford, dyer.

Samuel Parr, South Sherwood Street, Nottingham, aerated water manufacturer.

A. S. Ramage, Lincum Soap and Alkali Co., Weston, Cheshire, chemist.

Jno. Salaman, The Willows, Wennington, near Romford, Essex.

J. R. Savage, Frankford P.O., Philadelphia, Pa., U.S.A., manufacturing chemist.

F. T. Schreiber, 78, Hampden Street, Bolton, Lancashire, analyst.

G. A. Seaward, St. George's Brewery, Commercial Road, E., brewer.

Evan W. Small, Cavendish Crescent North, The Park, Nottingham, teacher of science.

Andrew Taylor, 37, South Clerk Street, Edinburgh, manufacturing chemist.

C. O. Trechman, Cliff Terrace, Hartlepool, cement maker.

C. H. Trimmell, New Malden, Surrey, manufacturing chemist.

Arthur Wharton, Gas Works, Basford, Nottingham, laboratory assistant.

#### CHANGES OF ADDRESS.

Capt. W. de W. Abney (d.o. St. Alban's Road), Willestie House, Wetherby Road, South Kensington.

Jas. Beveridge (d.o. Lincum), Ely Paper Mills, Cardiff.

H. E. Bunker (d.o. Neafth), 25, Albany Road, Manor Park, Essex.

C. Denston (d.o. Bourverie Street), 3, Westminster Chambers, Victoria Street, S.W.

Dr. Geo. Eschellmann (d.o. Widnes), O. 7, No. 8, Mannheim, Germany.

P. C. Gilchrist (d.o. Wolverhampton), Palace Chambers, 9, Bridge Street, Westminster, S.W.

W. L. Gunn (d.o. Stratford), c/o Messrs. Christian Thomas & Bros., Broad Plain Soapworks, Bristol.

Dr. D. B. Hewitt (d.o. Prestwich), Winnington House, Northwich, Cheshire.

Thos. Hilditch (d.o. Openshaw), 25, Wellington Street, Bradford, Manchester.

John Holloway (d.o. Highbury Grange), Kupferwerke, Magdamack, Servia.

J. J. Hummel, Cavendish Villas, Woodhouse Cliffe, Leeds.

A. H. Hutchinson (d.o. East Dulwich), Boylston Villas, Derwent Grove, Champion Hill, S.E.

W. E. Kay (d.o. Manchester), c/o Messrs. Crum & Co., Thorncliffebank, Glasgow.

Jno. Lennox (d.o. Glasgow), Cloncurry Copper and Smelting Co., Queensland.

T. H. Muras (d.o. Newcastle), Sydenham Villa, Defoe Road, Lower Tooting, S.W.

T. H. Reeks (d.o. Wellington Buildings), 71, Chelsea Gardens, Chelsea Bridge Road, S.W.

H. Rivett (d.o. Littleborough), Wharf Street Mill, Lancashire Hill, Stockport.

Dr. H. Schupp (d.o. Ludwigshafen), Messrs. Schott, Segner and Co., 26, Princess Street, Manchester.

J. W. Smith (d.o. Halifax), West Street, Paddock, Huddersfield.

G. Watson, jun., d.o. St. Vincent Street, 16, East Nelson Street, Whitevale, Glasgow.

J. H. Wright (d.o. Eglinton Chemical Co.), Scafield House, Montgomery Street, Irvine, N.B.

John Young (d.o. Glasgow), Kincaid House, Milton of Campsie, N.B.

## Death.

J. H. Hadrell, 1 o Wilderspool, Warrington.

## London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: David Howard.

Committee:

Sir F. A. Abel,  
H. E. Armstrong,  
W. Crowder,  
C. Graham,  
S. Hall,  
A. K. Huntington,  
R. Messel.

R. E. R. Newlands,  
B. Redwood,  
T. Royle,  
John Spiller,  
G. C. Trowby,  
J. Willmott,  
J. Williams.

Local Sec. and Treasurer: Thos. Tyrer,  
Garlen Wharf, Church Road, Battersea, S.W.

MEETINGS, SESSION 1885—First Monday in each month (unless otherwise indicated).

April 13. (First Monday after Easter)—Mr. W. J. Dibdin—"Further Notes on the 'Radial' Photometer, and the Proposed Standards of Light."

May 1.—Messrs. Giles and Shearer—"The Real Strength of Aqueous Solutions of Sulphurous Acid."

Messrs. C. Napier, Hake, and Mook—"The Stassfurt Salts Industry, and its bearing on other Industries."  
Discussion on Professor Munro's paper published in January number of the Journal, "On the Manifold Value of Filter-Pressed Sewage Sludge," read January 5.

June 1.—Messrs. Salaman and W. de Vere Mathew—"The Influence of Phosphates upon Fermenting Worts."

July.—The Annual General Meeting.  
Notices of papers and communications for the meetings to be sent to the Local Secretary.

Meeting held March 4, 1885.

SOME EXPERIMENTS UPON THAT PART OF THE PATENT OF MR. F. B. RAWES FOR THE RECOVERY OF SULPHUR, ETC., WHICH DEPENDS UPON THE ACTION OF CARBON-DIOXIDE UPON SODA WASTE OR SULPHIDE SUSPENDED IN A LIQUID.

BY WM. JOEL KEMP.

In the process in question the reliance is upon carbon-dioxide as the chemical agent for the elimination of hydrogen-sulphide, the carbon-dioxide being applied in the manner detailed in the patent taken out by Mr. Rawes early in the year 1882. It appeared to me that the suspension of the sulphide in a liquid "intermedium," and the systematic agitation specified, were definite, and most important advances upon all previous attempts in the same direction, and therefore the process seemed to claim an especial interest.

My experiments now to be described were carried out during August and September, 1882, and the proposition started with was:—

"Given pure carbon-dioxide to operate with, whether hydrogen sulphide would be produced sufficiently free from admixture with carbon-dioxide to be utilisable as a source of sulphur or sulphuric acid; and whether practically the whole of the sulphur existing as sulphide could be eliminated by the method."

The waste used was partially oxidised, and contained a total of 21.41 parts of sulphur in 100 parts of dried waste, three-fifths of the sulphur being convertible into hydrogen sulphide by treatment with hydrochloric acid.

In making the first experiment a measure of moist waste equal to about 20cc. was divided into three approximately equal parts, and each part placed in a wide-mouthed bottle with some bi-carbonate of soda solution as an "intermedium," the use of an "intermedium" being part of the process alluded to. Each

of the three bottles (Fig. 1) was fitted with a cork pierced with three holes—a larger one in the centre through which passed a glass tube with its lower end dipping into the liquid, and reaching at the upper end to about eight inches above the rim of the bottle. This tube was sufficiently wide to admit of the easy working of a stout wire rod which passed through it, and which was bent at the lower end in such a manner as to form a stirrer.

Through the smaller holes glass tubes were passed in such a way as to represent the usual arrangement of the Woulfe's bottle. The bottles were then connected in series, and the first of the series attached to a Kipp gas generating apparatus charged with marble and hydrochloric acid, and provided with a wash bottle containing water.

The exit tube of the third bottle was connected with two flasks coupled together in series, charged with copper sulphate solution slightly acidulated with sulphuric acid. Next the second flask was a drying bottle containing concentrated sulphuric acid, and then a small weighed flask with caustic potash to retain any  $\text{CO}_2$  that might pass over unabsorbed.

The upper end of each stirrer worked in a bearing, and was fitted with a pulley. The pulleys were coupled together by elastic bands, and one of them

FIG. 1.

attached by the same means, to a small Griscombe (electric) motor. The three bottles, simulating the "desulphurizers" described in the patent, were placed in a water bath, provided with a source of heat, the complete arrangement being shown in the accompanying illustration (Fig. 2).

The motor was started and a slow stream of  $\text{CO}_2$  admitted, and after some time the copper sulphate solution darkened in colour, and upon heating the water bath to about  $45^\circ \text{C}$ . a decided precipitate appeared. The pressure of carbon dioxide was only sufficient to propel a very weak current of gas through the apparatus, and the stirrers worked only slowly, in consequence of the pulleys requiring readjustment. After five hours the experiment was stopped, the receivers disconnected from the desulphuring bottles, and a current of air aspirated through the former.

The copper sulphide was then collected on a filter, dissolved, and precipitated with caustic potash, and the copper weighed as oxide. The potash bottle was also weighed, and from the results the respective weights of hydrogen sulphide and carbon-dioxide that were absorbed were calculated as follows:—

$$\begin{aligned} \text{H}_2\text{S} &= .081 \text{ grams} = 96.43 \text{ per cent.} \\ \text{CO}_2 &= .003 \text{ " } = 3.57 \text{ " } \end{aligned}$$

These results appeared satisfactory as to the percentage composition of the resulting gases, but the small amount of gas expelled determined me in continuing the experiments to provide for a greater pressure of carbon dioxide, which was accomplished by fitting a tube by a cork into the neck of the Kipp apparatus, to the upper end of which tube was fixed by a pierced cork a cylinder open at the top to serve as a reservoir.

The working of the pulleys and stirrers was very much improved, so that in the later experiments it was easy with a current from three Groves' cells to give them a very rapid rotation.

The receiving arrangement was also remodelled as shown in Fig. 3.

The exit tube A from the last desulphurer of the series was bent at an obtuse angle at B, and was kept cool with moistened filtering paper during the experiments to condense any slight amount of moisture. C and D were charged with a known volume of a standard solution of copper sulphate, and were placed in a water bath kept at a temperature of about  $40^\circ \text{C}$ . E contained a small quantity of lead nitrate to indicate if any hydrogen sulphide passed the copper sulphate unabsorbed. F was a drying bottle with concentrated sulphuric acid, G with caustic potash to take up the

FIG. 2.

carbon-dioxide, and in the test tube H was a small quantity of concentrated sulphuric acid to prevent the entrance of carbon-dioxide and moisture from the air.

The receivers C and D were in duplicate, and the duplicates were used alternately in order that it might be possible to wash and dry one set before recharging with copper sulphate solution, during which time the other set could be used. This arrangement was necessary to render it possible to estimate the amounts of the gases evolved at various stages of the operation. The method adopted to estimate the copper sulphide precipitated was as follows:—

After each stoppage the receivers were disconnected from the desulphurizers at I, and the exit tube of the latter was plugged. Air was then aspirated through the receiving apparatus C to H, after which the contents of the tube D were added to those of the flask, and the whole shaken up together, and a small portion of the solution quickly filtered through a dry filter. 10cc. were then taken by a pipette from the filtrate, and the copper, after reduction by sulphurous acid, was precipitated by an excess of ammonium thiocyanate. The precipitate being filtered off the excess of ammonium thiocyanate was

estimated by titration with silver nitrate, and the hydrogen sulphide calculated from the results.

In carrying out this method for the estimation of the residual copper, some slight oxidation of the copper sulphide may have occurred during the aspiration, and the filtration of the copper solution; but the error, if any, due to this cause must have been

until the issuing gas almost ceased to precipitate any sulphide from the copper solution.

The liquid was then poured off and a portion of the residue, after being washed and dried at 100° C., was distilled with hydrochloric acid, the distillate being received into a solution of copper acetate, which proved that the solid residue was practically

FIG. 3.

insignificant. In the second experiment (*i.e.*, the first under the new arrangement) two desulphuring bottles were employed instead of three, as before; and a larger quantity of waste was operated upon.

A measure (about 20cc.) of the moist waste was placed in each bottle, the bicarbonate of soda solution added, the stirrers rotated, and a current of carbonic anhydride passed in. The results at stated intervals are given in the following table:—

Number of Stoppages.	Number of Hours run.	Weight in grammes of Gases collected.		Percentage composition of Gases collected.	
		H <sub>2</sub> S	CO <sub>2</sub>	H <sub>2</sub> S	CO <sub>2</sub>
1	2	·2067	·0217	90·93	9·07
2	1½	·4371	·0200	95·62	4·38
3	1	·3117	·0000	77·76	22·24
4	1	·4530	·1250	78·37	21·63
5	2	·2200	·0200	91·66	8·34
6	3	·1695	·0170	90·88	9·12
7	1	·2968	·0100	88·12	11·88
8	3	·6350	·0700	90·07	9·93
9	2½	·1130	·0100	91·17	8·83
	17	3·1458	·1437	87·63	12·37

The above table shows some remarkable differences in the composition of the escaping gases—for instance, see Nos. 3 and 4, where the percentages of hydrogen sulphide were only 77·66 and 78·37 respectively.

In these cases the battery was weak, and the agitation consequently insufficient to utilise fully the quantity of carbon-dioxide being passed in. This point will be referred to later on. Whilst Nos. 5 and 6, where the gas expelled is small in amount, show that the pressure of carbon-dioxide was weak owing to the need of replenishing the supply of acid in the generating apparatus.

As the residue from this experiment was not exhausted of sulphide, it was further subjected to treatment with carbon-dioxide for nine hours, and

exhausted of sulphide, as no precipitate of copper sulphide was formed—a mere trace being indicated by a slight brown colouration at the edge of the copper solution. And this trace was probably due to iron-combined sulphur existing originally in the waste, which would of course not be acted upon by carbon-dioxide.

The next trial was conducted with one desulphuring bottle only, the receiving arrangement remaining as before.

Two measures of moist waste (each equal to about 20cc.) were acted upon with results stated in the following table:—

Number of Stoppages.	Number of Hours run.	Weight in grammes of Gases collected.		Percentage composition of Gases collected.	
		H <sub>2</sub> S	CO <sub>2</sub>	H <sub>2</sub> S	CO <sub>2</sub>
1	1	·1743	·029	83·25	16·75
2	1½	·2130	·071	76·65	23·35
3	1	·2762	·121	70·00	30·00
4	1	·2700	·213	56·25	43·75
5	2	·5038	·228	68·55	31·45
6	2½	·6371	·185	77·22	22·78
7	1½	·5712	·188	71·80	28·20
8	2	·1965	·307	61·77	38·23
9	3	·3301	·208	62·00	38·00
10	2	·2216	·120	64·80	35·20
	17½	3·7261	1·673	69·01	30·99

From the above table it will be seen that when approximately the same quantity of waste formerly acted upon in two connected desulphuring bottles, was now operated upon in one, a much larger percentage of carbon dioxide passed through, showing that the distance travelled by the gas in its ascension through the suspended waste has a marked effect upon the respective proportions of hydrogen sulphide and carbon dioxide coming off. As might be supposed,

the deeper the column of "intermedium" (containing a given quantity of waste) the better the result in hydrogen sulphide.

For this reason, and also because a great absorption of carbon dioxide takes place at first starting, it is evident that an arrangement, as suggested by the patentee, which permitted the use of two or more desulphurisers in series, and an interchange in their order, would be most desirable. In such a case, the excess of carbon dioxide passing from the first would be utilised by the fresher waste in the second, third, etc. The propriety is also pointed out of having the desulphuring vessels as deep as circumstances will allow.

The next experiment was carried out with a view to ascertain whether, by greatly increasing the number of points of contact between the ascending gas and the suspended particles of waste, a greater current of carbon dioxide could not be forced in without danger of its passing away unabsorbed; and to this end, one desulphuring bottle was charged with five measures (each about 20cc.) of waste and a bulk of intermedium, reaching to the same height as in the previous experiments.

The results obtained were as follows:—

Number of Stoppages.	Number of Hours run.	Weight in grammes of Gases collected.		Percentage composition of Gases collected.	
		H <sub>2</sub> S	CO <sub>2</sub>	H <sub>2</sub> S	CO <sub>2</sub>
1	1	5721	0315	87.83	12.17
2	2	4388	0310	89.55	10.45
3	1	2150	0505	81.13	18.87
4	1½	9121	0430	95.51	4.49
	8½	19383	1960	90.80	9.20

During the first 3 to 4 hours the absorption of carbonic anhydride was very great, and the quantity of hydrogen sulphide expelled comparatively small, owing to the hydrate of lime contained in the waste, which required saturating by the carbon dioxide before the latter could act to any extent upon the calcium sulphide.

This absorption of carbon dioxide had been anticipated, of course, and noticed in the earlier experiments, but in the present case it was more marked, in consequence of the much larger quantity of waste being operated upon.

At this point another desulphurer, similarly charged to the first, was attached thereto, and the experiment continued, the respective weights and proportions of the gases evolved being annexed:—

Number of Stoppages.	Number of Hours run.	Weight in grammes of Gases collected.		Percentage composition of Gases collected.	
		H <sub>2</sub> S	CO <sub>2</sub>	H <sub>2</sub> S	CO <sub>2</sub>
1	1	7310	019	97.48	2.52
2	2	12530	037	97.13	2.87
3	3	9475	039	96.05	3.95
	2½	23345	085	96.85	3.15

From these two last experiments I found, as surmised, that by acting upon a larger quantity of sulphide in a given bulk of "intermedium," it was possible to pass in a larger supply of carbonic anhydride, and consequently to obtain a richer result in hydrogen sulphide, almost free from admixture with carbon dioxide.

It now occurred to me that if, from the small apparatus with which I was working, I could obtain a current of hydrogen sulphide in sufficient quantity to burn from a jet, it would be an attainment not devoid of interest, and to that end I now proceeded to adapt my apparatus as shown in Fig. 4.

Three desulphuring bottles were now charged, each with about the same quantity of waste as in the last experiment, and the gases evolved from the desulphurisers were made to pass through three bottles, A, B, and C (all containing solution of normal sodium carbonate), which represent the purifiers designed by the patentee for the absorption of waste carbon dioxide. D, E, and F contained absorbents of hydrogen sulphide, and were used to prevent the escape of the gas, should it not be obtained in sufficient quantity to burn from the jet, as I had no fume closet of sufficient size available. H was filled with dried calcium chloride.

Four cells of a Groves' battery were connected with the motor, which gave the agitators considerable velocity, and a current of carbon dioxide was forced through the apparatus. After a short time, clip K was opened, and, on a light being applied to the platinised burner G, the gas burned freely, with a flame some 2½. to 3 in. long.

The experiment was repeated several times with varying degrees of success, and the best results were obtained when the agitation was most efficient.

There was a marked relation between the speed of the agitators and the quantity of carbon dioxide absorbed on the one hand, and of the hydrogen sulphide evolved on the other. As an instance: upon one occasion the agitators were only working at a moderate speed, and under those conditions it was not possible to keep the gas burning on account of the quantity of CO<sub>2</sub> present, my arrangement of normal sodium carbonate solutions not being sufficient to absorb all the carbon dioxide when a strong current of that gas was passing. On putting on, however, an additional cell, which probably doubled the speed of the stirrers, the carbon dioxide was absorbed and the issuing gas burned freely. It is thus evident that the efficiency, or otherwise, of the agitation is sufficient to make all the difference between success and failure.

The short piece of tubing L, surrounding the burner, steadied the flame and prevented its floating away as it was sometimes inclined to do, doubtless through the presence of carbon dioxide. I suppose the piece of outside tubing lessened the dissipation of heat from the burner, so that the gas and air met at a higher temperature than when the tube was dispensed with.

With regard to the application of heat to the desulphurisers, it was found that by heating the water bath in which they were to about 45° C., the commencement of the evolution of hydrogen sulphide was accelerated.

In preparing each of the foregoing experiments, the addition of the bicarbonate of soda solution to the waste caused an immediate evolution of hydrogen sulphide, showing, I think, that the view is correct that the bicarbonate acts as a carrier of carbon dioxide to the sulphide.

Remembering that my method of passing in the gas, although as convenient as I could readily adopt, is not to be compared in point of efficiency with

arrangements that could be made with apparatus upon a larger scale, and taking this into consideration, together with the results obtained, it must, I think, be confessed that the action of carbon dioxide upon soda waste, under the conditions prescribed by Mr. Rawes, is a question of considerable interest.

Although I have spoken above of the action of carbon dioxide upon calcium sulphide, I have not overlooked the researches of Dr. Divers and others upon the changes which take place in alkali waste, etc., but I have sought simply to give the practical results of my experiments, leaving out of consideration, at the present time, those intermediate steps by which the final results may have been attained.

FIG. 4.

The present investigation being very incomplete on certain points, it was intended to have followed it up by other experiments calculated to throw light upon the question as to the best temperature at which to keep the desulphurisers, and, again, others to show the differences in composition of both the solid and liquid contents of the bottles, before and after treatment of definite amounts of waste and intermedium, with definite quantities of carbon dioxide, for definite periods of time, etc.

Pressure of work, however, in other directions has, so far, prevented these intentions being carried out.

#### DISCUSSION.

Mr. CRESSWELL said, that the weak point in Mr. Kemp's interesting paper consists in his silence as to efficient means for procuring that pure carbonic acid on a commercial scale on which he relies for his reaction. Without such provision the practical aspect of the paper would at once disappear. He might inform the meeting that while working the Schaffner and Helbig process at Messrs. Chance's Works, sulphuretted hydrogen had been made on such a large scale that it had been used in flames sometimes more than a foot long for making chamber acid, and burnt as freely as coal gas. In decomposing waste by limekiln or flue gases this direct burning was impossible, and a supplementary process such as that of Mr. Claus' became necessary.

#### THE TREATMENT OF CERTAIN PHOSPHATIC MINERALS OF THE TYPE KNOWN AS "REDONDA" PHOSPHATES.

BY W. J. WILLIAMS.

In 1878 the problem was laid before me of how to deal with the phosphates of alumina and iron known

as "Redonda" phosphate, so as to produce therefrom marketable products.

Two methods at once suggest themselves: (a) solution in mineral acid, (b) furnacing with alkalis or alkaline salts.

In considering the possibilities of solution the solvents are practically reduced to two—viz., hydrochloric and sulphuric acids.

Hydrochloric acid was quickly dismissed, as this acid dissolves the phosphate but does not decompose it, and on neutralisation of the acid solution, phosphate of alumina and iron is simply re-precipitated. The only advantages derivable from this method of treatment are, first the siliceous matter can be

separated by decantation, and second, the phosphate of alumina and iron is re-precipitated in a very finely divided condition.

**Treatment with Sulphuric Acid.** In this method I was unable to devise any improvement on the well-known process of the late Mr. Peter Spence, who dissolves in moderately strong sulphuric acid, separates from the siliceous matter by decantation or filtration through sand, adds ammonium or potassium sulphate in the necessary proportions, and then crystallises out the alum thus produced, leaving a mother liquor of phosphoric acid mixed with sulphuric acid. It is, however, very difficult to separate the whole of the alum by crystallisation from this strongly acid solution; many devices for obtaining thorough crystallisation were only partially successful, and in consequence the mother liquor of phosphoric acid is largely contaminated with sulphuric acid and considerable quantities of alumina. The alum obtained contains too much iron for the market, which renders its disposal a difficult matter.

Other methods are known for the treatment of "Redonda" by concentrated sulphuric acid, leaving the alumina and iron in an insoluble condition and separating phosphoric acid more or less mixed with sulphuric acid, but on investigation these did not give sufficient encouragement to warrant adoption, as by these processes the alumina does not seem obtainable in a marketable condition.

The "solution" processes in acid being thus eliminated, I then turned my attention to alkali.

Solution in caustic soda promised well, as sodic aluminate and sodic phosphate are formed, the iron oxide and sand being left as an insoluble residue. This method had to be abandoned, as it is covered by former patents; further, the costliness of the solvent was a serious obstacle to its commercial success.

I then turned my attention to "fusion" or furnacing methods.

The published patents of these "furnacing" methods are very numerous. They include furnacing with sodium hydrate, sodium carbonate, and sodium sulphate with and without silica, carbon, and other additions. Furnacing with sodium sulphate (salt cake) and coal was well known to me, having taken out letters patent for such a process some years before, when dealing with a kindred phosphate of alumina and iron known as "Alta Vela" phosphate.

Before going into the details of furnacing processes it is now time to consider the preparation of the raw mineral. Intimate mixture with the alkaline salt is, of course, of great importance, which necessarily pre-supposes fineness of division. "Redonda" is of a very porous texture and generally contains from 20% to 25% of moisture and combined water. In this raw state it is difficult to grind, as it binds and chokes the mills. This objection is obviated by first calcining or roasting it. There are of course many ways of performing this, but as only a low red heat is required the most economical method is the following. The rough rock mixed with about 10% of fuel, preferably coke, is thrown into a vertical cylindrical cupola, this calcines freely and thoroughly, splitting up into small lumps, which are friable, and can be ground to any desired degree of fineness through French stones; for furnacing purposes, however, it is quite sufficient to pass the calcined "Redonda" through ordinary "edge runners," together with the alkaline salt and coal or coke if required. This gives a sufficiently finely-ground and intimate mixture for practical purposes.

The intimately mixed materials, "Redonda," saltcake and coke are then thrown into a reverberatory furnace and roasted until the mass begins to "set" and get "sticky." This operation is analogous to the "black ash" operation of the Leblanc process, and takes about the same time, two hours being sufficient for each charge, about three-quarters of an hour on the "back" and one and a quarter on the "front" bed of the furnace. It requires, however, more attention from the workman, for as the mixture does not fuse together or "ball" it must be turned over at frequent intervals, so as to continually expose fresh surfaces to the action of the flames. When drawn it is a little "sticky," but on cooling breaks up into small lumps; indeed, it might be more accurately described as coarse powder. Towards the end of the furnacing operation the fire must be urged fiercely and air admitted freely that the sulphur may be oxidised to sulphurous acid and driven off, otherwise the sulphides become a serious nuisance in lixiviation. The finished charge should also be allowed to cool before being transferred to the vats. The sulphurous acid is utilised as shown below.

This method of furnacing with saltcake and coke produces, when the furnace ash is lixiviated, a solution of tri-sodium phosphate and sodium aluminate, according to the following equation:—

leaving in the lixiviating vats an insoluble residue of sand and ferric oxide.

In this way the phosphoric acid is separated as tri-sodium phosphate and the alumina as tri-sodium aluminate, but now arises the question, "What is the value of these products?" As they stand they are unmarketable except in comparatively small quantities. It is obvious then that they must be converted into saleable articles, say alumina hydrate and calcium phosphate.

First I will deal with the alumina.

Originally I purposed treating the mixed solution

of tri-sodium aluminate and tri-sodium phosphate directly with the sulphurous acid gas evolved from the furnace, precipitating alumina as hydrate and reducing the tri-sodium phosphate to di-sodium-hydrogen phosphate, with formation of sodium sulphate, according to the equation:—

and filtering off the alumina hydrate. This, however, did not answer, for I found that instead of obtaining alumina hydrate, a retrograde action took place, the phosphoric acid re-combining with the alumina, and a mixture of alumina phosphate with alumina hydrate was precipitated. The proportion of phosphoric contained in this mixture of alumina phosphate and hydrate varied considerably, but was always above 21%. Whether the lye from the vats was taken highly concentrated at say 60 T.w., or diluted down to even 10 T.w., still the alumina precipitated invariably contained phosphoric acid. This difficulty was finally overcome by the expedient of crystallising out the tri-sodium phosphate from the "vat liquor," and having thus separated the tri-sodium aluminate, treating it with the sulphurous acid gas from the furnace and precipitating the alumina hydrate. The quantity of phosphoric acid precipitating along with the alumina hydrate was, of course, dependent on the completeness of the crystallisation of the tri-sodium phosphate. By a second crystallisation, or in other words, concentrating the mother-liquor from the first crystallisation, and again crystallising out the tri-sodium phosphate, a mother-liquor of tri-sodium aluminate was obtained containing only 15% to 12% of the phosphoric acid *originally in the vat liquor*, or about 98% of the tri-sodium phosphate could be crystallised out of the vat liquor.

The tri-sodium aluminate thus obtained was then treated with the sulphurous acid gas from the furnaces by means of ordinary condensing towers, which were carefully packed with flints. The sodic aluminate liquor was forced to the top of the towers and allowed to percolate through the flints, where it met the ascending stream of sulphurous acid gas, which reacted on the liquor, precipitating alumina and leaving sodium sulphate in solution. The towers were very carefully packed, so that the precipitated alumina should not choke up the interstices between the flints, but practically there was little difficulty in keeping them clear. The alumina was then filtered at 90 to 100 lb. pressure and washed in filter-presses, and dried by steam heat under a partial vacuum at a temperature not exceeding 240°F. or 116°C. It was found to be practically impossible to wash the alumina completely free from soda salts, either in the washing presses, or by agitating the alumina with successive doses of water and re-filtering.

The sodium sulphate was evaporated to dryness and utilised for fresh furnacings.

#### TRI-SODIUM PHOSPHATE.

The sale for this product is very limited. It was therefore decided to convert this into calcium phosphate. But this conversion could not possibly be a commercial success unless the soda were recovered in at least as valuable a form as that in which it was used for furnacing. Therefore the obvious method of treating the tri-sodium phosphate with calcium chloride, with production of sodium chloride, was out of the question.

The method of using freshly-burned lime after the manner of "causticising" was experimented with for a considerable time on the laboratory scale; taking all due precautions for obtaining well-burned lime free from carbonate, it is possible to produce a high strength calcium phosphate, containing phosphoric acid

equal to from 90 to 95% tri-calcium phosphate and a thoroughly causticised solution of soda. On the manufacturing scale this was, however, found to be impossible. The best results were obtained by the device of "repeated treatments;" that is, each batch of phosphate of soda liquor was treated successively with three doses of lime, and each charge of lime was treated in turn with three successive doses of phosphate liquor, in such a way that the partially causticised liquor was finally treated with fresh lime, and the partially phosphated lime was finally treated with strong sodium phosphate, so that in the case of the liquor there was a very large excess of caustic lime,  $\text{CaO}$ , and in the case of the lime there was a very large excess of sodium phosphate present in the final treatments. In this way the liquors were fairly well causticised, but the precipitate could not be completely phosphated, the results averaging about 34% phosphoric acid, equal to 74% tri-calcic phosphate. This precipitate always contained a large proportion of calcium carbonate, even when the process was conducted in closed vessels and freshly and thoroughly burned lime was carefully chosen. Working in closed vessels under pressures varying up to 40 lb. per square inch did not improve matters.

The use of chalk, with or without pressure, gave no better results, the average being much the same as with burnt lime. As this 74% phosphate was little better than natural phosphates, it was not considered satisfactory.

The next trial was made with calcium sulphate as gypsum. This gave somewhat better results than either lime or calcium carbonate, giving a product of from 80% to 85% tri-calcium phosphate when dried, the liquor resulting from the decomposition being, of course, sodium sulphate.

Using solid matter in suspension in water, such as lime, chalk, or gypsum, it appeared as though it were impossible to get a sufficiently intimate admixture of the sodic phosphate liquor and the suspended lime or lime-salt, so as to get thorough re-action and complete decomposition. It then became a question as to what soluble calcium salt would best produce a high-strength calcium phosphate, and at the same time produce a soda salt either of the same commercial value as salt-cake, or one that would serve equally well for future use in the furnacing operation. As before mentioned, calcium chloride was out of the question.

My friend, Mr. W. A. Hills, then suggested the use of the soluble calcium di-sulphides, obtained from old oxidised "vat waste" or "alkali waste." I have made several experiments with the "yellow liquor" produced by treating old "alkali waste" with water, but the calcium phosphate formed was always contaminated with more or less sulphur. This led me to consider the idea of "blowing" or further oxidising the "alkali waste" until the di-sulphides were converted in hypo-sulphites or thio-sulphates. In the oxidising process for the recovery of sulphur, the waste is blown until the calcium sulphides are converted into di-sulphide and thio-sulphates, but for this purpose continued the "blowing" or oxidation until the di-sulphides were converted to the fullest practicable extent into thio-sulphates, and on lixiviation yielded, not the "yellow liquors" of the sulphur recovery process, but a colourless solution of calcium thio-sulphate. If on lixiviation of the oxidised alkali waste it was found that the liquors still contained any appreciable quantity of calcium di-sulphide, then sulphurous acid gas was forced into the liquors until the di-sulphide was converted, thus—

This solution of sodium thio-sulphate re-acts perfectly on a solution of tri-sodium phosphate, producing a

tri-calcium phosphate of about 96% and sodic thio-sulphate, which on evaporation can be utilised for furnacing.

Here I may call attention to a somewhat remarkable re-action noticed during the experiments, which will, I believe, be novel to many. As before remarked, it was originally intended to treat the vat liquors directly with sulphurous acid gas from the furnace and thus precipitate alumina, at the same time reducing the tri-sodium phosphate to di-sodium-hydrogen phosphate and forming sodium sulphite, but this method was afterwards abandoned when it was found that alumina phosphate was precipitated with the alumina hydrate. While working on this principle, however, another difficulty arose, caused by this peculiar re-action. The mixture of sodium sulphite and di-sodium-hydrogen-phosphate was treated in the ordinary way with a sufficient quantity of calcium thio-sulphate to form di-calcium phosphate, on the supposition that the calcium thio-sulphate would decompose the di-sodium-hydrogen-phosphate, but would have no action on the sodium sulphite, thus precipitating di-calcium phosphate and leaving a mixture of sodium sulphite and thio-sulphate. This re-action did indeed occur, but it was accompanied by a re-action between the sodium sulphite and the calcium thio-sulphate, precipitating calcium sulphite and forming sodic thio-sulphate, so that a mixture of calcium sulphite and di-calcium phosphate was precipitated, leaving sodium thio-sulphate in solution, thus—

As a mixture of calcium sulphite and di-calcium phosphate is of no great market value, some method had to be adopted to prevent this production of calcic sulphite. This was effected by injecting air through the mixed sodium sulphite and di-sodium hydrogen phosphate until the sodium sulphite was "blown" to sodium sulphate, which is not decomposed by calcium thio-sulphate, the re-action then taking place being—

The di-calcium phosphate was then filtered and washed, and the mixed sodium sulphate and thio-sulphate evaporated to dryness for future use.

When it was found that the tri-sodium phosphate must be separated from the sodium aluminate by crystallisation this difficulty was partially obviated, as to produce tri-calcium phosphate it was only requisite to re-dissolve the crystals and treat the solution with the proper proportion of calcium thio-sulphate to supply three equivalents of calcium for each equivalent of phosphoric acid present. If di-calcium phosphate, however, was required, then the solution of the tri-sodium phosphate crystals was reduced to di-sodium hydrogen-phosphate by the sulphurous acid gas, the sodic sulphite oxidised by injected air to sodic sulphate, and the mixture of di-sodium-hydrogen-phosphate and sodium sulphate treated with sufficient calcium thio-sulphate to supply two equivalents of calcium for each equivalent of phosphoric acid. The di-calcium phosphate was then filtered at 90 lb. pressure and well washed, and there was no difficulty in washing this precipitate practically free from soda salts. The phosphate was then dried, like the alumina hydrate, by a steam heat under a partial vacuum, temperature not exceeding 240° F. or 116° C. By these processes the alumina is obtained as hydrate, and the phosphoric acid as di-calcium phosphate, with recovery of soda as sodium sulphate sulphite and thio-sulphate, which, when evaporated to dryness, are available for use in future furnacings.

This process, however, had certain objections. First, there was the carriage of alkali waste; then

in shooting the waste into the vats (furnished with perforated false bottoms for "blowing" or oxidising) it was found that it clogged and caked in masses, so that the air could not penetrate equally through the bulk, and consequently large quantities entirely escaped oxidation; so that, as a practical result, the quantity of lime obtained as calcium thio-sulphate was about 15 to 20 on the total alkali waste. This small yield was only attained by a heavy outlay in labour, and rendered the process practically inoperative unless it could be carried on in close contiguity to an alkali works, where the waste could be "blown" without removal from the vats. Not only does this save the labour of moving the waste, but, owing to the porous or honeycombed condition in which the waste is left, it permits free access of air all through the mass, so that the sulphides are more completely oxidised, and the proportion of soluble calcium thio-sulphate obtained is larger.

While this method was being elaborated I carried out numerous experiments for obtaining a re-action between the "Redonda" phosphate and sodium chloride. Direct fusion of the phosphate of alumina and iron with sodium chloride gave no result beyond a small liberation of hydro-chloric acid gas. It then occurred to me that if free hydrogen were present to combine with the chlorine of the salt a re-action might be established, which proved to be the case.

The cheapest and most practical way of presenting free hydrogen to a mixture of phosphate and salt seemed to be to decompose steam by means of red-hot coke, while the combustion of the coke would serve to raise the temperature to the necessary degree, the coke thus serving a double purpose. Coke was used in preference to coal, that the escaping hydrochloric acid gas might be kept clear for afterwards precipitating the alumina.

A mixture in the proper proportions of phosphate, salt, and coke was now prepared, ground and mixed together in edge runners, moistened, laid out in thin cakes, and dried. The cakes were then stacked in a small cylindrical furnace of 3 feet internal diameter and 6 feet high, lined with 9 in. brickwork, and enough coke added to serve as fuel, and fired. When the mass got red-hot a current of steam and air was forced through. After repeated trials good results were obtained, and it was found that on an average, 90% of the phosphoric acid in the "Redonda" was converted into tri-sodium phosphate. The re-actions are expressed by the equation—

On lixiviation the tri-sodium phosphate and sodium aluminate are dissolved out from the "ash," and the tri-sodium phosphate separated from sodium aluminate by crystallising as before described. The mother-liquor, consisting of sodium aluminate, is decomposed by the hydrochloric acid gas, precipitating alumina and reproducing sodium chloride. This decomposition is effected in condensing towers, in the same way as previously described. The alumina hydrate is then filtered and washed, the sodium chloride evaporated for use in a fresh furnacing. With the use of sodium chloride the production of calcium phosphate is much simplified, for calcium chloride can now be used to decompose the sodium phosphate. To produce tri-calcium phosphate, the crystals of tri-sodium phosphate are re-dissolved and calcium chloride added so that three equivalents of calcium are present for each equivalent of phosphoric acid. To produce di-calcium phosphate the dissolved tri-sodium phosphate crystals are first treated with sufficient hydrochloric acid to take up one equivalent of soda, producing di-sodium hydrogen-phosphate and chloride of sodium, and the

mixture then has calcium chloride added in the proportion of two equivalents of calcium to one of phosphoric acid, producing a semi-crystalline di-calcium phosphate, which is filtered and washed in the ordinary way. This precipitated di-calcium phosphate is of very high strength, containing about 95% of di-calcium phosphate, or about 50% of phosphoric acid, equal to 100% tri-calcium phosphate.

It may be remarked here that calcined "Redonda" phosphate is freely soluble in ammonium citrate, and when applied, thus calcined and finely ground, as a fertiliser to the soil has been found of great efficiency, especially with roots and grass.

This method could be indirectly applied to the recovery of the phosphoric acid in the "basic slags" of the Thomas Gilchrist process. The slags could not be furnace directly with sodium chloride in an atmosphere of hydrogen, or with sodium sulphate and carbon, for the sodium phosphate thus formed could not be extracted from the "ash" by lixiviation, as the caustic lime present in the ash would decompose it, precipitating calcium phosphate in the vats, along with the oxides of iron and manganese. By the methods of Messrs. Gilchrist Thomas and Tynan, however, the slag is dissolved in hydro-chloric acid and a large proportion of the phosphoric acid precipitated from the solution as ferric phosphate; and this ferric phosphate is then decomposed by strong sulphuric acid, forming a mixture of free phosphoric and sulphuric acids and sulphate of iron, which is insoluble in excess of strong sulphuric acid, and can be separated by filtration. It appears to me that it would be more economical to recover the phosphoric acid of this ferric phosphate, in the form of tri-sodium phosphate, by furnacing with salt in the presence of hydrogen, and decomposing the tri-sodium phosphate by calcium chloride, precipitating calcium phosphate and recovering sodium chloride for use in future furnacings.

Notices of papers and communications for the meetings to be sent to the Local Secretary.

Meeting held Tuesday, February 24, 1885.

SIR HENRY ROSCOE IN THE CHAIR.

THE CHAIRMAN: Before beginning the usual business of the meeting, I wish to state that an international committee has been formed for the purpose of erecting a statue to the memory of Nicolas Leblanc, the well-known discoverer of the Leblanc process of alkali making. A large number of Continental scientific men and chemical manufacturers has been appointed a committee for the purpose of endeavouring to obtain subscriptions, with the addition of Colonel Gamble, Mr. Weldon and myself, as representing this country. I feel sure that every member of this Society is so well acquainted with the claims of Nicolas Leblanc, and with the enormous value of his discovery to English industries, that I believe you will all agree with me in thinking that it would be only proper for this Section

in particular, situated in the midst of a district which has profited so largely by this discovery, to send our acknowledgments to the committee, and assist them in helping forward the movement. I shall be glad to receive any subscriptions to the fund, and beg to commence the list with a contribution of five guineas.

## THE HISTORY OF CREOSOTE, CEDRURET AND PITTACAL.

BY PROFESSOR C. SCHÖRLEMMER, F.R.S.

CREOSOTE was discovered by Reichenbach\* in the year 1832; he found it in the tar, as well as in the pyrogenous acid obtained by the dry distillation of beechwood, and describes it as a colourless liquid, which strongly refracts light, and begins to boil at 203°. It has an unpleasant, penetrating smell, reminding one at the same time of that of smoked meat, and possesses the characteristic property of coagulating albumin. Meat, after being dipped in an aqueous solution of creosote for half an hour or one hour, may be dried in the open warm air of a summer's day without undergoing putrefaction. He showed samples of meat thus prepared at the meeting of the German Naturalists in Vienna, and people who had made many voyages found it very tasty.

Reichenbach continues: "Now, as pyrogenous acid by itself produces this effect, as well as the tar-water—which, according to public statements, may be prepared by lixiviating the soot of our stoves and chimneys—there cannot be any doubt that creosote is the *antisepic, conservative principle* contained in these liquids as well as in smoke. As we further know from Pliny's tales that the Egyptians prepared their mummies with pyrogenous acid, which they obtained by carbonising the aromatic woods of their hot climate, we perceive that the ultimate cause dwells in the new body, creosote being the mummifying element. The so-called costly spices used by the ancients at the same time, were probably nothing but an expedient to mask with other perfumes the unpleasant empyreumatic smell dwelling in all the products of carbonisation."

Of the word *creosote*, which he proposed as the name for the new substance, he says: "I derive it from its property to preserve meat, being the most striking, the most peculiar, and that which has been known from the most ancient times. *κρέας* means in Greek flesh, the genitive being *κρέατος*, or *κρέατος*, and contracted *κρέως*; *σώζω* means, I preserve or save; both words may etymologically be combined to the word *creosote*, meaning the meat preserving or saving from decay."

Very soon after, Runge† discovered carbolic acid in coal-tar, and Launcey‡ obtained from it his hydrate of phenyl, which later on was found to be identical with Runge's compound. But as to the relation existing between creosote and carbolic acid no clear views were held, and a confusion arose, which was kept up with an obstinacy unparalleled in the history of our science, and lasting for many years.

Runge described carbolic acid as an oily, very refractive liquid, which, like creosote, produces a white spot on the skin, after which it becomes glistening and peels off. Like creosote, it precipitates albumin and protects organic bodies from putrefaction, but it does not appear to be identical with smoky principle, inasmuch as meat preserved by it has an abominable taste. It differs, further, from creosote by being an acid and forming salts.

In spite of this, Reichenbach thought to recognise his creosote in carbolic acid; he was the more inclined to do so as he had previously stated that creosote was also found in coal-tar, animal-tar and amber-tar, almost as abundantly as in wood-tar.§

Runge could not agree to that; he maintained the peculiarity of carbolic acid, and described the properties by which the two bodies differed as exactly and correctly as it was possible at that time.

Laurent mentions in his well-known Memoir the great resemblance of phenylhydrate with carbolic acid and creosote, and says: "It is even probable that Runge's carbolic acid is nothing but impure phenylhydrate." Creosote, however, was regarded by him as a totally different body, on account of its higher boiling point, its inability to crystallise, even at 27°, while phenylhydrate forms crystals melting at 34° to 35°, and carbolic acid when cooled down deposits sometimes needles melting above 15°. Chlorine converts creosote into a brown substance, containing no chloropheniseic acid (trichlorophenol), which is readily obtained from phenylhydrate. Moreover, the action of bromine, nitric acid and ferric chloride on the latter compound is quite different from that on creosote.

These distinct statements did not prevent Gmelin to refer in his hand-book to Laurent's investigation, in order to prove his preconceived opinion that creosote, carbolic acid and phenylhydrate were identical, and differing only by a certain degree of purity.

Gmelin's views were accepted by most chemists, the more readily as Reichenbach himself believed in the identity of creosote and carbolic acid, and stated that he had obtained the former from coal-tar.

Soon carbolic acid was found in commerce under the name of creosote; the few chemists who were in possession of the genuine article could easily convince themselves of the peculiarity of creosote, but this was not sufficient to produce a change in the general accepted view. If about 40 years ago a chemist ordered creosote from a German firm he always obtained carbolic acid.\*

About that time, Gorup-Besanez examined a sample of "crystallised creosote," and compared it with one from Blanko in Moravia, where Reichenbach had discovered it. He found both bodies totally different, but he had not sufficient material for a more exhaustive investigation.\*\*

A few years after he obtained again genuine creosote from Blanko through Batka in Prague, and found that it did not give pieric acid by the action of nitric acid, and chlorine did not convert it into chloropheniseic acid, which can so easily be obtained from carbolic acid. On treating creosote with hydrochloric acid and potassium chlorate, no chloranil  $C_6Cl_4O_2$  was formed, but a similar body containing hydrogen.††

Hardly any attention was paid to these observations; Gmelin mentions them in his hand-book, only to add that if Gorup-Besanez wanted to prove the existence of creosote, he ought to have examined that which he had prepared himself, and not a sample obtained from a wholesale druggist.

Two years later, Gorup-Besanez published a more extended investigation, in which he confirmed the statements of Reichenbach, Runge and Laurent. The portion boiling at 203° to 208° had the same composition as the creosote sent by Reichenbach to Liebig, and which Etting had analysed. By the action of chlorine he obtained bodies, which he called

chlorinated xylenes, and formulated as *pentachlorobenzene*,  $C_{13}H_2Cl_5O_3$ , and *hexachlorobenzene*,  $C_{13}H_2Cl_6O_3$ . He pointed out that they bore great resemblance to Stadelé's chlorinated quinones.\*

Although this research did not clear up the chemical nature of creosote, yet it furnished a complete proof of the fundamental difference between creosote and carboic acid.

At the same time Völkel published a paper on the same subject; he examined creosote which was manufactured from wood-tar in Solothurn. He purified it by repeated treatment with boiling potash solution, precipitation by sulphuric acid and subsequent distillation. The oily liquid thus obtained boiled at  $202^\circ$  to  $208^\circ$ , and exhibited the general properties of Reichenbach's compound: differing from it, however, by its higher specific gravity and its composition,† as the following results of the analyses of Ettling, Gomp-Besanez and Völkel show:—

	Creosote from Blansko (mean of 8 analyses).	Creosote from Solothurn (mean of 3 analyses).
Carbon .....	75.21	72.15
Hydrogen .....	7.90	7.10
Oxygen .....	16.89	20.15
	100.00	100.00

Völkel's creosote was therefore decidedly different from Reichenbach's, and his results, instead of contributing to the solution of the creosote question, made it more complicated, the more so as Deville, who analysed creosote which he had obtained from Reichenbach, and such which Pelletier had prepared, had got results agreeing with those of Völkel‡.

Völkel was of opinion that Gomp-Besanez's creosote had not been sufficiently purified, wherefore the latter subjected 500 grammes to the treatment, which Völkel had employed until only a few grammes were left. The amount of carbon had now diminished 15, and that of hydrogen only 0.2 per cent.

The smell of the purified product resembled that of guaiacol, which is obtained by the distillation of guaiacum resin. Gomp-Besanez says that the resemblance of guaiacol with creosote had already been noticed, and it appeared to him probable that from the latter by repeated treatment with potash guaiacol might be obtained.§

In the same year (1855) Williamson published the results of experiments which Fairlie had made, in order to find whether coal-tar creosote consisted of carboic acid.¶ He thus discovered cresyl hydrate  $C_7H_8O$ , the next higher homologue of phenyl hydrate. This new compound, boiling at  $203^\circ$ , or almost at the same temperature as beechwood creosote, although not being mistaken for the latter, yet made the subject still more confused.

A new chapter in the history of creosote begins with Hlasiwetz's researches, "On Beechwood-tar Creosote and the Products of the Distillation of Guaiacum Resin."¶

By the action of potash on creosote from Blansko he obtained a crystalline potassium compound  $C_8H_9KO_3 + 2H_2O$ , which when decomposed by sulphuric acid yields a colourless, oily liquid ( $C_8H_{10}O_2$ ), having an aromatic smell, a burning taste, and boiling at  $219^\circ$ .

The same body, which he called *creosote-guaiacol* or *creosol*, was found in the products obtained by distilling guaiacum resin, together with its lower homologue *guaiacol*  $C_7H_8O_2$ , which boils at  $200^\circ$ , and which had already been obtained by Deville and Pelletier.

Hlasiwetz was led to the conclusion that wood-tar creosote is decidedly not impure phenyl-hydrate, as Guélin assumed; it is also totally different from coal-tar creosote, consisting chiefly of cresyl alcohol. Most probably it is a kind of ether corresponding to the potassium compound, and containing the radical  $C_8H_{11}$ , which would simply explain why creosote contains a larger percentage of carbon than creosol.

In the following year Duclos published a paper on cresyl alcohol, which he had obtained from coal-tar, but also found in the tar of the Giessen Gasworks, where only wood, chiefly pinewood, was used.\*\*

This is, as Gomp-Besanez pointed out, in contradiction to all we know of the products formed by the distillation of wood. Neither he nor other chemists had succeeded in detecting phenols in wood-tar. If Duclos found such bodies we must come to the conclusion that pinewood yields products totally different from those obtained from beechwood.

Meanwhile Gerhardt†† had recalculated the formulae of the chlorinated xylenes in  $C_8H_5Cl_2O_2$  and  $C_8H_4Cl_3O_2$ , regarding them as the homologues of the chlorinated quinones. Hlasiwetz's results gave a support to the new formulae, and Gomp-Besanez intended to commence a new investigation, but was prevented, inasmuch as he could not get a new supply of creosote from Blansko; this source was exhausted, and different samples which he obtained from other sources under the name of beechwood creosote were found to be nothing but carboic acid.

In 1864, Hugo Müller brought an important contribution to the history of our subject. He examined English creosote, which was prepared in London from *Stockholm-tar*, and appeared, as he wrote to Gomp-Besanez, to be identical with that from Blansko. He isolated from it Hlasiwetz's creosol, which by the action of iodine, phosphorus, and water, or hydriodic acid, was resolved into *methyl iodide* and *homopyrocatechin*  $C_7H_6O_2$ , the higher homologue of pyrocatechin  $C_6H_6O_2$ ‡‡.

The investigations of Völkel, Gomp-Besanez, Hlasiwetz, and Müller, who had examined wood-tar creosote from three different sources, furnished the most convincing proofs that it has nothing in common with coal-tar creosote. In the way of a general agreement, there remained only the statement of Reichenbach that coal-tar contained creosote, and that of Duclos that wood-tar contained phenols.

Reichenbach, however, never proved his statement, and as Duclos was the only chemist who found phenols in wood-tar, the great creosote question appeared now to be settled, and yet it did not come to rest.

In 1865, A. E. Hofmann examined different commercial products which he had obtained from several firms as genuine beechwood creosote. He obtained from them phenyl hydrate, and from this he prepared chloranil ( $C_6Cl_4O_2$ ) and picric acid. Not being acquainted with the researches of Hlasiwetz and Müller, he denied the existence of an individual creosote, it being nothing else but impure phenyl-hydrate, while the chlorinated xylenes consisted of a mixture of chloranil (tetrachloroquinone) and chlorinated phenols. The names creosote and hexachloroxylene had to be removed from the list of chemical compounds, while it might be convenient to retain the name creosote for the commercial article.§§

Gomp-Besanez replied that Hofmann, in order to prove his statements, ought first to have convinced himself that he had really to do with genuine creos-

§§ Journ. Prakt. Chem. 96, 225.

sote. Without difficulty he might have found that the druggists whom he mentions could not, though with best intentions, have supplied him with beechwood creosote, as it had disappeared from the German market long ago. Thus he would have not come into the position to prove, what was already known for a long time—viz., that carboic acid was sold under the name of creosote.\*

This episode had, however, an issue as unexpected as pleasing, for Fresenius informed Gorp-Besanez that the "Verein für Chemische Industrie in Mainz" manufactured creosote from beechwood-tar, and brought it into commerce. In examining it, Gorp-Besanez found that it was different from Blansko creosote, but probably identical with that examined by Völkel, inasmuch as the chief portion boiled at 199-207°. He succeeded in isolating from it a large quantity of *guaiaacol* and some *creosol*. By acting on the crude creosote with hydrochloric acid and potassium chlorate, he obtained *tetrachloroguaiacone* ( $C_7H_2Cl_4O_2$ ) and *tetrachlorocresone* ( $C_8H_2Cl_4O_2$ ), the latter being identical with hexachloroxylene. These compounds behaved like homologues of tetrachloroquinone, and might therefore be regarded as derivatives of the two yet unknown homologues of quinone, *guaiacone* and *cresone*, standing in the same relation to *guaiaacol* and *creosol* as quinone to hydroquinone:

On treating the crude Rhenish creosote with iodine, phosphorus and water, Gorp-Besanez obtained methyl-iodide and pyrocatechin, which undoubtedly were derived from *guaiaacol*:

The latter bearing such a great resemblance to pyrocatechin, it appeared that it and *creosol* were the true homologues of pyrocatechin and not of hydroquinone. There was, however, one fact in opposition to this view—viz., pyrocatechin boiling at 240°, or higher than its homologues.

Gorp-Besanez found, further, that the yield of pyrocatechin and methyl iodide falls short of that indicated by the above equation, a large quantity of a thick oil, containing phosphorus, being found, possessing such an abominable smell, that he hesitated to examine it more closely, its odour adhering to the clothes most obstinately, that it made one socially impossible.

As already stated, Hlasiwetz assumed the existence of the compound  $C_8H_8(C_9H_{11}O_2)_2$  in Moravian creosote; Gorp-Besanez found that the composition of the Rhenish creosote agreed best with the assumption it contained the radical  $C_8H_5$ †.

This view was opposed by Marasse,‡ because if the portion of the creosote boiling between 199-208° contained this radical, it ought by the action of potash to yield allyl alcohol or a similar compound. But such a body had not been observed. Moreover, *guaiaacol* being undoubtedly the methyl-ether of a kind of phenol, and it being known that such bodies are not decomposed by potash, Gorp-Besanez's view can be the less maintained as he purified creosote by repeated treatment with potash and hydrochloric acid, without altering essentially its composition.

But why does the percentage composition of Rhenish creosote differ so considerably from that of *guaiaacol* or *creosol*?

	Creosote.	Guaiaacol.	Creosol.
Carbon .....	72.11	67.71	69.58
Hydrogen .....	7.16	6.45	7.24
Oxygen .....	20.70	25.81	23.18
	100.00	100.00	100.00

The most simple answer is furnished by the assumption that creosote contains, besides *guaiaacol* and *creosol*, some compounds containing more carbon and less oxygen, but boiling at the same temperature as these two bodies.

Marasse was able to prove this hypothesis; he found that the portion of creosote boiling below 199° contained common phenol or phenyl hydrate  $C_6H_5O$ , and the higher boiling portion its homologues *cresol*  $C_7H_7O$ , or *cresyl* hydrate and *phlorol*- or *phoryl*-hydrate  $C_8H_9O$ , together with *guaiaacol* and *creosol*, which are the creonometyl ethers of pyrocatechin and homopyrocatechin, which is proved not only by their decomposition with hydriodic acid, but also by the fact that they can be obtained from the latter simply by heating them with potash and methyl iodide.

As the initial members of both series have different boiling points, that of the first member of the *guaiaacol*-group agreeing with the second of the phenol group, it becomes self-evident that the most volatile portion of creosote must consist only of common phenol:

PHENOL SERIES.	Boil. Point.	GUAIACOL SERIES.	Boil. Point.
Phenol... $C_6H_5OH$ ...	181°		
Cresol... $C_7H_7OH$ ...	203°	Guaiaacol... $C_7H_5(OH)$ ...	200°
Phlorol... $C_8H_9OH$ ...	220°	Creosol... $C_8H_7(OH)$ ...	219°

The creosote analysed by Gorp-Besanez was a mixture of *guaiaacol* and *creosol*; one consisting of equal parts having a composition nearly agreeing with that found by him:

Carbon.....	72.41
Hydrogen.....	6.99
Oxygen.....	20.69
	100.00

Moravian creosote contains a larger percentage of carbon, being essentially a mixture of *creosol* and *phlorol*.

Marasse further proved that tetrachloroguaiacone and tetrachlorocresone are not derivatives of *guaiaacol* and *creosote*, but stand to *cresol* and *phlorol* in the same relation as chloranil or tetrachloroquinone to phenol. We call them now tetrachlorotoluquinone and tetrachloroxyloquinone or tetrachlorophlorone.

The Rhenish creosote was also examined by Bräuninger; he found in his sample only traces of phenol, less than two per cent. of *cresol*, and no *phlorol* whatever. In the sample which Gorp-Besanez had examined he also found but little *cresol*, and still less *phlorol*§, whilst Mendelssohn and Tiemann|| observed a large quantity of the latter compound in the portion of Rhenish creosote boiling at 220°. Another sample which Gorp-Besanez obtained, was examined by Biehle, who found it to consist almost entirely of *creosol*.¶

Creosote is, therefore, a mixture of *guaiaacol* and *creosol* in varying proportions, with larger or smaller quantities of phenols. The presence of the latter shows that beechwood creosote is more closely related to coal-tar creosote than it was formerly believed. Characteristic of the former is the presence of the *guaiaacols*, which do not occur in coal-tar, and which are undoubtedly produced by some aromatic bodies found only in wood, and which have been examined by several chemists.\*\*

Creosote contains, besides phenols and guaiacols, some bodies which are insoluble in alkalis. Mendelssohn and Tiemann\* found *homopropocetidin-dimethylether*, or *methylcreosol*,  $C_6H_3(CH_3)(OCH_3)_2$ , which boils at  $214-218^\circ$ , whilst, according to Hofmann, the higher boiling portion contains the following compounds, which dissolve in alkalis:

Pyrogallol-dimethylether  $C_6H_2(OCH_3)_3.OH$   
Methylpyrogallol-dimethylether  $C_6H_3(OCH_3)_2(OH).OH$   
Propylpyrogallol-dimethylether  $C_6H_3(C_2H_5)(OCH_3)_2.OH$

These researches cleared up the chemical nature of two interesting compounds, which were also discovered by Reichenbach.

*Cedriret* does not exist, ready formed, in wood-tar, but is obtained from it, according to Reichenbach, by the following process: The rectified oil, which is obtained by distilling the tar, is freed from acetic acid by means of carbonate of potash, and then treated with a solution of caustic potash. The alkaline solution is saturated with acetic acid, by which some oil separates out, while another portion is obtained by distilling the aqueous solution. When about one-third has passed over, that which follows is tested with a solution of ferric sulphate. As soon as this produces a red precipitate—the distillate is collected separately. All bodies which easily part with oxygen produce this red colouration; as, for instance, a solution of chromate potash and tartaric acid; on adding it a red precipitate, consisting of needles, appears after five minutes, and soon fills the whole liquid, from which it slowly deposits, leaving a colourless solution. The same change is produced by the oxygen of the air.

This body is *cedriret*, which name is composed of *cedrium*, tar-water, and *rete*, net, because its crystals group themselves on the filter like a net.†

According to Reichenbach, it is insoluble in water, spirits of wine, and all ethers, but dissolves in pure sulphuric acid, containing no nitric with an indigo blue—and in creosote with a purple colour.

Alcohol separates it from the latter solution in the form of a crystalline precipitate.

Berzelius says that it is only obtained in a small quantity; and its preparation requires that skill in the treatment of empyreumatic bodies in which its discoverer has so often proved his mastery.

Völkel did not succeed in obtaining it from the wood-tar which he examined.‡

In the year 1872, Liebermann|| examined a blue substance, which he called *cerolignone*  $C_{16}H_{14}O_6$ , and which obtained by purifying pyroigneous acid by means of potassium bichromate.¶ He found it to be insoluble in most solvents; sulphuric acid dissolved it with a cornflower-blue colour and phenol with a red colour. Alcohol or ether precipitate it from the latter solution in beautiful steel-blue needles. Reducing agents convert it into colourless *hydrocerolignone*  $C_{16}H_{18}O_6$ , crystallising in monoclinic prisms. On heating the latter with hydrochloric acid to  $200^\circ$ , it is resolved into methyl chloride and *hexhydroxydiphenyl*  $C_{12}H_4(OH)_6$ , which, by red-hot zinc dust, is reduced to diphenyl  $C_{12}H_{10}$ .

These facts prove that hydrocerolignone is the tetramethyl-ether of hexhydroxydiphenyl, and cerolignone the corresponding quinone. Liebermann gives the following formulæ:—

Marx,\* and afterwards Hofmann,\*\* pointed out that Liebermann's compound was nothing else but Reichenbach's *cedriret*. Hofmann obtained it by the action of potassium chromate or nitric acid on a high boiling oil from wood-tar, in needles having a violet lustre, and says Reichenbach had described it, not only with a precision which leaves nothing to wish for, but also so attractively, that one must be astonished how a body possessing such charming properties had been neglected for thirty years—nay, almost entirely forgotten.††

Liebermann recognised the identity of *cedriret* with *cerolignone*, to which he had given this name on account of its blue colour, of its being obtained from wood, and possessing the characteristic properties of a quinone. He says that as Reichenbach had described it as a red body obtained from a high boiling oil, from which neither Völkel nor he were able to prepare it, while *cerolignone* had a blue or violet colour, and was derived from pyroigneous acid, he had formerly come to the conclusion that *cedriret*, if existing, would probably be nearly allied to, but not identical with, *cerolignone*.‡‡

Hofmann, who prefers Reichenbach's shorter and very characteristic name, found afterwards that *cedriret* is a derivative of the dimethyl-ether of pyrogallol. On adding potassium bichromate to its solution in acetic acid, the liquid becomes hot, and some is filled with needles, which, in transmitted light, appear red, and in the reflected splendidly steel-blue. It may also conveniently be prepared by adding hydrochloric acid to a boiling alkaline solution of potassium chromate and pyrogallol-dimethylether, the liquid changing into a mass of slender reddish-brown needles.§§

Its formation is explained as follows:—

*Pittacal*.—Reichenbach observed that the oil from wood-tar, which is heavier than water, after being freed from acids by caustic potash, yields, when stirred up with baryta water or baryta hydrate, a blue colour, which gradually changes into black. The new body thus formed he called *pittacal* (*ὑπὲρ το καλόν*), but gives no particulars as to its mode of purification, etc., reserving it for a further communication. He describes it in the following words: "When obtained from a solution as a precipitate or separated by evaporation, it unites to a hard, brittle, dark-blue mass, having a dull fracture; like indigo, it assumes a metallic reflection on rubbing, which varies from a coppery lustre to a pure brass-yellow, according to its purity, being in the mean a splendid golden yellow, in striking contrast to the dark blue ground. This golden lustre appears also on allowing the moist mass to dry up. When pure, this lustre predominates in such a way that it cannot be obtained without it; everything moistened by it—porcelain, glass, paper, linen, etc.—appears gilded on a blue ground.

"In the pure state it is taken up by water; on standing, the dilute solution deposits dark violet flakes, and becomes colourless; but if concentrated nothing separates out. It dissolves freely in acetic acid, with an auroral colour; alkalis throw it down again. On pouring an aqueous solution into concentrated potash-lye, the bright blue colour changes into a violet blue,

and after some time blue flakes separate, consisting of fine needles.

"It combines with metallic oxides, and gives with sugar of lead, tin-salt, sulphate of copper ammonia, acetate of alumina, blue precipitates having a violet lustre."

Reichenbach adds: "It thus appears to have a technical value, which for Europe, where no indigo is produced, may become of an incalculable importance. Preliminary experiments have shown that it may be fixed on cotton or linen by means of acetate of alumina or tin-salt, producing a fast blue, not being affected by light, water, soap, ammonia, urine or wine."\*

Reichenbach did not publish any more on this subject; nor did Volkel succeed in preparing it,† and it was almost forgotten, till Grätzel, a chemical manufacturer in Hannover, re-discovered it. On oxidising the high-boiling fraction of wood-tar oil he obtained a colouring matter, which he gave to Wichelhaus for further examination.‡

On purifying the crude product a compound was obtained crystallising from alcohol or dilute acetic acid in orange needles, dissolving in ammonia with a blue, and in the alkalis with a purple colour. On allowing the solution to remain in contact with air, or more quickly on passing carbonic acid into it, blue salts are precipitated, which also occurs on the addition of salt-solutions. They are soluble in pure water. If the precipitation proceeds slowly a skin is first formed on the surface, exhibiting a splendid metallic lustre. The salts of calcium, barium, magnesium, and tin give blue precipitates, often showing a golden reflection; those produced by calcium and magnesium being soluble in pure water.

The compound dissolves in concentrated sulphuric acid with a purple colour, changing by heat into a bright, pure blue.

The orange crystals are not Reichenbach's pittacal; the latter consisting of the salts of this body, which Wichelhaus, in order to avoid mistake, and in remembrance of Reichenbach's body, called *eupiton* (ev, beautiful).

Hofmann § then found that this compound, which he calls *eupittonic acid*,  $C_{22}H_{22}O_6$ , is obtained by heating the dimethyl-ether of pyrogallol with hexachlorethane and alcoholic potash to  $160^\circ$  to  $170^\circ$  :—

It is also produced by melting a mixture of the dimethyl-ethers of pyrogallol and methylpyrogallol with caustic soda in the presence of air|| :—

Reichenbach obtained from the oils of wood-tar a liquid, which he called *picamar* (*pice amarum*). It boiled at  $285^\circ$ ; had a faint but unpleasant smell, and a bitter, burning taste, which afterwards becomes cooling like that of peppermint. Its alcoholic solution gave with baryta-water pittacal, and from this it appears that his picamar contained the dimethyl-ethers mentioned above.

Eupittonic acid contains two atoms of hydrogen, which can be replaced by metals. On adding caustic soda to its alcoholic orange solution it changes into splendid blue colour, a flocculent precipitate of *sodium eupittonate*  $C_{12}H_8O(OCH_3)_3(KO)_2$  separating out, which after 24 hours is converted into a mass of

small prisms having a beetle-green lustre. *Barium eupittonate*  $C_{12}H_8O(OCH_3)_3O_2Ba$  is a precipitate consisting of blue needles, while the lead-salt crystallises in pale reddish needles.

At the same time when Reichenbach carried out his researches at Blankse, Runge in Berlin examined the constituents of coal-tar, in which he discovered carboic acid, as already mentioned. On treating coal-tar oil with milk of lime, and allowing the solution to remain in contact with air, it coloured red, a compound being formed which he called *rosolic acid*. It is easily seen that the formation of this body is quite analogous to that of pittacal. But the constitution of these two compounds is also perfectly analogous, rosolic acid or *aurin*, as it is now called, being obtained by heating carboic acid with oxalic and sulphuric acids :—

Now eupittonic acid is *hermethorhglaurin*—

which is proved by its formation as well as by its properties. On heating aurin with ammonia, it is converted into *paracarsaniline* :—\*\*

In the same way Hofmann converted eupittonic acid into *hermethorhglaurin*—

which dyes silk, sulphurated wool, and tannated cotton a fine and pure blue.

I have already stated that the guaiacols, as well as the other methyl-ethers contained in wood-tar, owe their origin to certain aromatic compounds contained in wood. Although we know but little of them, we have got a clue to their formation. The cambial liquid of the conifers, from which in spring and early summer the new wood is formed, contains the glucoside *coniferin*  $C_{16}H_{22}O_8$ , which, as Haarmann and Tiemann†† have shown, is by the action emulsin, a ferment contained in almonds, resolved into grape sugar and coniferyl alcohol :—

Coniferyl alcohol, as well as coniferin, are converted by oxidation into *vanillin*††, which gives to vanilla its delightful smell.

The same compound may, as Reimers and Tiemann found, be obtained from wood-tar, it being formed by heating guaiacol with chloroform and caustic potash‡‡ :—

By a similar reaction Reimers has converted phenol in salicylaldehyde, a constituent of the aromatic oil of the meadow-sweet (*Spiraea Ulmaria*).

I may further mention that Griffiths has found phenol in the stem leaves and cones of the Scotch fir (*Pinus sylvestris*)§§.

Pelletier and Walter, in the introduction to their Memoir on the chemical investigation of the products formed in the preparation of illuminating gas from resin, say that chemical operations which are carried on a large scale permit the observation of certain phenomena, and the investigation of certain laws, as well as the discovery of new products, which by

working in the laboratory would have escaped our notice. Chemical industry, which, in its advance, uses theories as scouts, thus pays its debt to the chemists who have given assistance in furnishing them with new compounds for their examination, and thus extending the sphere of our science.

Thus the manufacture of coal-gas has made chemists acquainted with some new bodies of the greatest interest. Without gas-lighting we should probably have yet to discover Faraday's liquid hydrocarbons (butylene and benzene), Kidd's naphthalene, and Dumas and Laurent's para naphthalene (anthracene).

It is scarcely necessary for me to enumerate here how many new and important bodies have since been obtained from coal-tar. This black, fetid substance, formerly a large, embarrassing bye-product, has now become of the highest importance for the production of most splendid colours. Hand-in-hand with the development of this new chemical industry went scientific researches, which, without the use of coal-gas, could never have been undertaken. For the chemistry of the aromatic compounds coal-tar has become an, as yet, inexhausted source for new bodies, and for the artificial preparation of such as hitherto found only in the organic world.

But also the investigation of wood-tar has largely contributed to the development of organic chemistry, as shown by the short historic sketch which I have laid before you.

What a revolution, not only in chemical industry, but also in dyeing, calico-printing, and even in agriculture, the discovery of coal-tar colours has wrought, I need not dwell upon here.

Hofmann said in his reports on the Exhibition of 1862, speaking of these new colours, that England may ere long send her cold-dried blues to indigo-growing India, her tar-distilled crimson to cochineal-producing Mexico, and her fossil substitutes for quercitron and sallow to China and Japan.

This prediction has not been quite fulfilled; but stranger events have happened. Who would then have thought that in less than twenty years the cultivation of madder would almost be a thing of the past? A few years ago a friend of mine, an eminent chemist, whose name I have mentioned to-day, was travelling in the South of France; after having seen all the sights of old Avignon, he requested his guide to take him to the madder plantations, but was told they did not grow any more. On being asked why, he replied, "Monsieur, it is now all made by machinery."

The cultivators of cochineal might almost say the same; the beautiful colour contained in it has not yet been obtained artificially, but substitutes have been found which have supplanted cochineal almost completely.

Coal-tar is not only a source of a host of most splendid colours, but also of valuable medicines—substitutes for quinine,—and the time is not far distant when quinine itself and other alkaloids will be prepared from tar. When on the Continent last year I visited one of the largest chemical works, where some new buildings were in course of erection. Asking my friend what they were for, he replied, "These are our future quinine works." What then was said as a joke may soon be said in earnest.

Rivers Bill," which has been prepared and brought into the House of Commons by Mr. Hastings, Earl Percy and Colonel Walrond, in November last, and which either in its present form or in an amended form may be brought before Parliament this session. Of the importance and at the same time the difficulty of legislating on this question, you are fully aware, and the differences of opinion which have been already expressed by various members of this Society, serve to show the obstacles which have to be overcome before the question can be satisfactorily solved. Before asking any of the members or strangers present to favour us with their views on this question, I may perhaps be allowed to state shortly the outcome of the opinions which have been so far expressed by various members of the Society in other sections.

[The Chairman then rehearsed the leading arguments of the principal speakers in the meetings of the other Sections where the subject had already been discussed. He then proceeded:]—

These abstracts give an idea of the various opinions entertained on this subject, so far as the discussion has already progressed. Of the advisability or necessity for some regular enactments there seems to be a general consensus of opinion. It also appears to be shown and felt that the application of a uniform standard to rivers throughout the country is inexpedient in the interests of the manufacturing industries of the country. Opinion is, however, much divided as to whether standards of purity of any kind should be adopted or not, and the difficulty of arriving at standards for every river, or rather for every part of every river, is too evident to need discussion. Nor is it necessary to enlarge on the essential difference between a rigid application of standards of purity in the case of the Alkali Acts, when every manufacturer is supplied with an unlimited quantity of the pure article—viz., air—and the application of similar unvarying standards to the case of water, which is supplied neither in quantity nor in quality to any manufacturers alike. The only course which then appears to be left open is to treat each case in its own merits, or to establish certain broader limits, which may be applicable to all cases. The proposal that county boards should take charge of, and have control over, the running water, whether pure or impure, in its district, appears to me to be the one most likely to lead to satisfactory results; each would be well acquainted with the necessities and possibilities of its particular county, and would apply under proper scientific advice, and with due control from a central authority as the Local Government Board, such regulations as are possible and suitable.

Alderman WALMSLEY, Chairman of the Rivers Conservancy of the Salford Corporation, said: I have come here to listen rather than to speak, because I want a great deal of help and guidance, and I thought I might elicit something from the discussion which would be of service to me in connection with the Borough of Salford. I have listened with a great deal of interest to the details of the Bill, as described by the Chairman, and to the results of the discussions of the various sections of your Society, and I must say that the outcome to my mind is one of almost hopeless confusion. Men of eminence in the scientific world seemed to vie with each other in contradiction, so that comparatively unscientific men, like myself, are at a loss how to deal with the practical difficulties which have to be contended with. I was very much struck with the remark of one gentleman to the effect that he would do away with all standards of purity, and require manufacturers to return the water to the streams in the same condition as they receive it. If that rule were carried out by all manufacturers up to

## DISCUSSION ON THE "RIVERS POLLUTION BILL."

SIR HENRY ROSCOE said: As you are aware, the Council of our Society has requested the various sections to consider and discuss "The Prevention of Pollution of

the source of the river, they would have pure rivers so far as regards manufactures. Public authorities, in dealing with this question, had to consider two aspects of it. Firstly, they had to take care, that nothing was done that would be calculated to interfere with the commercial interests too much; and, secondly, they had to consider the health of the community, and look at it in a similar manner as they did with regard to the smoke nuisance. I think anyone who has tried to deal practically with the difficulty of sewage pollution must feel very disheartened. I have at the present time an investigation going on as to the state of the Irwell from Manchester up to its source, and when I first began that investigation, I had some hope that the matter might be grappled with, but I find that the difficulty is greater and more serious than I had anticipated; still the Salford Corporation was determined to try to cope with it. With regard to the proposed Bill, it seems to me that we must not be too precise and anxious to carry out our own ideas. If we must have an Act that will be workable, it must be based on a give-and-take policy.

Dr. HEWITT: When we have to deal with rivers which have been for half a century or so the natural receptacle for the drainage of populous districts engaged in commerce, we come to a problem of great importance. If the owners of works so situated are to be deprived by legislation of the use of these natural outlets for the refuse of their manufactories, they are at least entitled to have some other outlet provided for them. No serious attempt had been made to put in operation the "Rivers Pollution Act" of 1876; that individuals had been made to suffer it was true, while others had escaped, and my belief is that it is premature to bring in another Bill for the purpose before that Act has been fairly tried. I believe that no good can be done until local influences are removed and some statesmanlike action taken for dealing with the question evenly and equally all over the kingdom. For my purpose I would prefer that the matter should be placed in the hands of officials sent down from London by the Local Government Board, because my experience of them has been that they are fairly free from prejudices; that they are always ready to hear both sides, and are exceedingly impartial. If it were left to such officials to decide what is practicable, I believe we might in a few years arrive at some satisfactory standard. For my own part I do not think that the evidence is sufficiently clear at present to furnish any definite standard. My idea is that a system of general inspection of rivers should be insisted upon, and that some such power should be given to the Local Government Board as was given to them under the Alkali Acts, in reference to noxious vapours, whereby they could require every manufacturer to adopt the best possible means of preventing the pollution of a stream. After all there can be no doubt that the greatest difficulty we have to contend with is the pollution by sewage, and I believe it is this difficulty alone that has led to so little being done to enforce the present Act. I very much admire the courageous, costly, and persistent efforts which the Salford Corporation have made to deal with their sewage. I understand that the cost incurred by the Salford Corporation is not far short of £200,000, and that their working expenses are very large. This is a very serious expense, even when dealing with the sewage of a town like Manchester; but how many towns are there which could afford such an outlay? But when all this outlay has been incurred, according to the last Report of the Commissioners on Rivers Pollution there is no known method of dealing with sewage so that the effluent from it is fit to drink, and that being so it seems to me a most cruel attempt on the part of Mr. Hastings

to fix standards of purity, quite beyond any one's power to realise, for his standard of colour has been shown to be infringed by bog and peaty water. I for one would agree to any practicable standard that would put manufacturers upon one basis. If you place one manufacturer under certain restrictions which increase his working expenses, and allow another manufacturer in the same business to carry on his work in his own way, you would very likely ruin one while you assisted the other. We should have an Act of Parliament that would be entirely independent of local influences, because the present Act is often put in force against manufacturers by men who are the greatest offenders themselves. What is needed is more knowledge, a central authority to carry out the law, and that the pollution of sewage should be dealt with first. The manufacturer should have the right to turn his effluent water either into the channel he has used for years, in as pure a condition as it is possible at reasonable expense to obtain, or, at least, if this be taken from him, he should have the right to use the sewers for which he is rated, provided that he does not injure the sewers or otherwise damage his neighbours.

Mr. ARTHUR JACOB, Engineer to the Salford Corporation, said that he had looked carefully through the draft Bill, and was familiar with the provisions of the Rivers Pollution Act of 1876. It is the duty of the Salford Corporation, as the conservators of the River Irwell within their borough, to exercise a jealous supervision over the river from its source to the point where the stream passes the borough boundary. The existing Act did not, however, prove to be very workable in respect of offences committed outside the borough, for if any pollution were cast into the stream above, it was almost impossible to secure the conviction of the offender, unless the polluting matter could be actually detected in that part of the stream which passes through Salford. In consequence of this imperfection in the old Act, the river had continued to silt up, and was now in almost as bad a state as it was ten years ago. He thought it was high time that some amendment was effected in the law for preventing river pollution. No community felt this necessity more keenly than those whose avocations obliged them to remain in the vicinity of that Stygian stream, the Irwell, the state of which was a disgrace to all who suffered its condition to continue as it is at present. Dr. Hewitt had told the meeting that Salford stood forth as an honourable exception, and as an example to other sanitary authorities on the stream. The Corporation had spent more than £200,000 on sewerage works to prevent the pollution of the stream; and he (Mr. Jacob) believed that the Corporation of Bolton were also carrying out works of such a magnitude as would deal with all the sewage of that borough. It is not to be wondered at that the Irwell and Mersey are in their present foul condition, when it is recollected that besides the polluted discharges from some hundreds of manufactories, the rivers receive the whole of the refuse from a population of one-and-a-half million of people. In the existing Act it was not made at all clear what was included under the term pollution, and this made it very difficult to bring offenders to justice; but the draft Bill is much more explicit in this respect, and in other respects is an improvement on the existing law, though it will have to be amended before it can be called a thoroughly practical measure. It is too Utopian in its character, and is calculated to press somewhat heavily on the manufacturing industries; and, moreover, its language is in some parts vague and involved, instead of being plain to all, and devoid of ambiguity. With regard to the standards set forth in the proposed Bill, the discussion of them

would be more for the chemist than the civil engineer. As particularised, the standards were not (as was before remarked), standards of purity, but limits of maximum impurity. Taking standard *a*, which provides that not more than one part of organic matter and three of mineral matter shall be found in 100,000 parts of water. This would prevent sanitary authorities from carrying out what is known as the duplicate system of drainage, by which all surface waters from streets, houses, courts, and yards are allowed to pass into the natural water-courses of the country. Compliance with this would involve a very burdensome restriction upon sanitary authorities, as the duplicate system usually led to considerable reduction of expense, and particularly in cases where the sewage has to be raised by steam power at the outfall. Professor Way has said "that so far as London sewage is concerned, and considering only the composition of the liquid which reaches the sewers in time of rain from the streets, it seems pretty certain that it would be as valuable in a manorial point of view as the ordinary contents of the sewers." Standard *b* does not appear to be too stringent where sewage can be treated by irrigation or downward filtration. It provides that not more than 2 parts of organic carbon, or 3 part of organic nitrogen, shall be present in 100,000 parts of any liquid passing into a river. At Croydon, a year's analysis of the effluent water from the Norwood irrigation fields gave an average pollution of 1515 of organic carbon, and 0.258 of organic nitrogen. This was from a pure clay soil, whilst at the Beddington farm the results were almost as good. He (the speaker) believed that these analyses had been made some years ago, and he understood that the purification was as effectual now as formerly. It seems impossible that the colour test, standard *c*, can ever be fully complied with. Rain-water passing from the surface of roads, and even from agricultural land, always retained a certain amount of colour, and not unfrequently carried a large body of grit and soil in suspension. It will be exceedingly difficult for owners of dye-works to comply with this standard, though no doubt they can effect a great improvement in the colour and quality of the water which they now send from their works.

Mr. HEYWOOD said: With regard to the standards of purity alluded to in the Bill, I should like for one moment to refer to the case of the firm I represent—viz., Messrs. Dickins & Co., of Middleton. We turn down the river Irk close upon a million gallons of refuse water per day, and at certain times it is, as Mr. Jacob said with regard to the Irwell in Manchester, as "black as ink" in consequence of our using such quantities of dyewood extracts, especially logwood, along with the various metallic salts, etc., and in addition to these, there is of course a host of commercial drugs and chemicals as well as the different aniline dyes. What plan could we possibly adopt to purify such a volume of water so as to conform to the requirements of the Act, especially Clause 9? If such a case were put before the framers of the Bill, would it not convince them at once that no dyeworks or printworks of any magnitude could possibly exist under such restrictions?

Mr. WM. THOMSON: The series of standards of pollution mentioned in the proposed Act applied indiscriminately to rivers would doubtless make highly polluted ones comparatively clear, but it would also furnish a basis for polluting pure ones. For rivers which are at present used for domestic water supplies, the standards of pollution allowed by the proposed Act are too high; whilst for highly polluted rivers, the main advantage which would be gained would be to make the streams less discoloured. The Irwell, which

I have closely examined on different occasions, and which may be taken as a typically polluted stream, is dark coloured, due mainly to solid sewage matter in suspension, which settles at parts of the river where there is little current, such as behind weirs and bends of the stream in which the water is comparatively still; usually there is no disagreeable smell from the river, but at some points of the stream in dry and warm weather objectionable smells arise. Still on settling this water, it can be used for many delicate manufacturing processes, and it would be usually much less costly for manufacturers to settle or filter the water they require to be clear from the river than to settle their refuse waters. It may be taken as certain on the one hand that it will cost the people of Lancashire immense sums of money to keep the Irwell a little less coloured than it is at present, and the advantage gained by so doing will be little or nothing. Dr. Hewitt considered that streams in which fish live should be kept pure, because they are sources of food supplies, and I agree with him; but on the other hand to purify some streams would absorb from, instead of yielding food supply to the people, and it will give them no adequate advantage for the expenditure. I think each river is of sufficient importance to be separately dealt with, and whilst it would be advisable that some restrictions should be enforced to preserve the purity as far as possible of all streams, such restrictions should be arranged and drawn up by the people who are more or less interested in each stream.

Mr. WATSON SMITH: I have arranged my ideas, for the sake of brevity, under the following subdivisions:—

I. (a) Some waters, streams and rivers, must be polluted according to the very nature of the industries—*e.g.*, bleaching, dyeing, printing and the like; and in some dyeing processes, as, *e.g.*, silk preparing, bleaching and dyeing, it is absolutely necessary that water-streams as pure as possible, and that even an atmosphere as pure as possible, shall be available.

(b) In a less degree is river pollution a necessity in other industries.

(c) Hence to prevent pollution entirely, would mean destruction of some industries and the maiming of others.

(d) The fixing of impracticable standards of impurity, is tantamount to destruction of these industries—*e.g.*, the colour standard of the proposed Bill would be very hard on dyers, and it must be remembered many of their colours have enormous tinctorial power, which means that an infinitesimal weight of dye would be represented by a distinct colour.

II. The nature of the pollutions will vary in different districts, will depend upon the prevailing industries in these districts. Thus, the Tyne will contain HCl, CaCl<sub>2</sub>, alkaline and earthy sulphides, finely divided sulphur, gypsum, etc., whilst the notorious Bradford-Beck will contain colouring-matters, and dyes, fatty matters, suds, oils, besides the solutions of the various mordanting materials, etc.

III. Hence fixed standards would be unjust, and indeed absurd, for we could imagine an alkali maker having a solitary works on the banks of one river, lined with cotton mills and weaving mills, polluting wholesale, whereas a whole district of alkali works on a river like the Tyne might be laid under legislation of prohibitory stringency.

IV. There are cases, where one can conceive pollution voluntarily abolished, being transformed into utilisation, but these cases are exceptional. Such transformation can usually only slowly take place.

V. To draw the line by enforcing utilisation, must be done intelligently and by those who know at least

as much as the manufacturers about their products, and who have scientific light enough to see ahead. Even then the scheme of enforcement should be at the first, at all events, of a not too stringent or sweeping character. Then, enforcement would be transformed into *co-operation*—as, witness the *Alkali Act* for greatly limiting the amount of hydrochloric acid thrown into the atmosphere.

VI. To *limit* pollution and keep it within certain bounds, differing for the various districts, is possible. The limits will ever grow narrower as scientific knowledge increases, and becomes more general.

VII. No pollution of water should be allowed which communicates pollution to the air in any way, or such that the water thus contaminated will act corrosively and destructively upon materials in the river or river-bed or banks, such as brickwork, cement, mortar, stonework, woodwork and the metals lead, copper and iron.

VIII. Water-courses of every kind running into and supplying reservoirs or lakes from which drinking water is drawn, or springs serving for drinking water, ought to be strictly preserved from contamination.

IX. It ought to be remembered that sewage contamination is the most virulent form in existence, outstripping in deleterious action by far that of the factories. If all the works on the banks of the rivers Irwell and Medlock were stopped, yet their waters would still remain badly poisoned by sewage, and so be made not one whit more potable than before.

X. I agree with Mr. Coleman of the Glasgow Section, in thinking the "standards of purity" which are proposed in the Bill to be brought before Parliament, for universal application, would be utterly impracticable. But, says Mr. Coleman, there is nothing to prevent standards being established for different parts of the country, by grouping the local authorities appointed under the Bill into districts.

XI. Hence I quite think the plan supported by Sir Henry Roscoe would be best and most likely to be successful—viz., to appoint county boards, for the prevention and mitigation of river pollution, aided by scientific experts, with whom they shall consult. A standard could then be framed for each district in each county, and just and fair legislation could then be enacted, and all pollutions either prevented, mitigated, or kept within due bounds, according to the varying local circumstances. No doubt it would follow that the Local Government Board would be the centre, where the proceedings of the Provincial Local Boards would be focussed, so to say, for purposes of general reports and for legislative government action.

Dr. HEWITT moved the following resolution:—"That the Prevention of the Pollution of Rivers Bill as proposed and brought into the House of Commons by Mr. Hastings is imperfectly drawn and Utopian in character, and could not in its present shape be carried into operation without serious injury to the manufacturing and commercial community; and the Manchester Section hereby requests the Council of the Society to oppose the Bill in its present form."

Mr. E. T. CUNLIFFE, in seconding the resolution, whilst fully agreeing with the terms of it, said: "I am of opinion in regard to our discussing this subject, that we must guard ourselves from appearing too obstructive towards any progress that may be attempted in the direction of the proposed Bill. If we take the old Act and see what it has effected, I think we are bound to admit it has done a great deal by preventing the putting into the streams of any solids. There has been no difficulty in carrying out this part of the Act, and the streams have been greatly improved by it. There can be no doubt that before any Bill can

be carried out, it must be less Utopian in character than the one proposed. To frame a Bill dealing with the purification of streams beyond the exclusion of solids is too great a step at once, and I am of opinion that such standards of purity only in the first instance must be fixed which experience has shown to be practicable, and that future legislation must be progressive. I would distinguish between sewage pollution and manufacturing pollution, the central authority should deal with the former as a matter pertaining to the public health; the latter might at some future date be dealt with by county boards, who might group the polluters and appoint a commission to investigate and report as to the best means of dealing with the subject.

The resolution was then put to the meeting and carried unanimously.

## HEMPEL'S METHODS OF GAS ANALYSIS.

BY DR. W. BOTT,

*The Owens College, Manchester.*

It is only a comparatively short time ago that gas analysis has at all been introduced into the rank and file of the *methods of technical analysis*, but in the short space of time since then and to-day it has gained a firm and important position amongst them, and in its application to several branches of industry has become as valuable and indispensable as any of our ordinary gravimetric or volumetric processes. The great end in view of all technical methods of analysis is rapidity; at the same time this must be combined with a sufficient degree of accuracy, and a great number of processes for technical gas analysis have been devised, more or less pretending to one or both of the above requirements. The principles of all these methods, we must bear in mind, had been established once for all by the founder of systematic gas analysis, Robert Bunsen, whose methods, as far as extreme accuracy and ingenious simplicity are concerned, stand unequalled above all others. Unfortunately, however, they are scarcely applicable to technical purposes, requiring, on the one hand, a great expenditure of time, and, on the other, a considerable degree of manipulative skill, which can only be acquired by long practice and experience. Still, the majority of technical methods that have been devised, and are being devised almost every day, are but modifications of the classical methods laid down by Bunsen.

The chemical principles involved in gas analysis are only few, simple, and common to *all* methods; the difference between such methods—that is to say, the advantage of one method over another—consequently cannot be due to the employment of new re-agents, but must be sought for in the mode of applying these re-agents, and mode of measurement of the gas, or, in short, in the form of the apparatus devised for the purpose. We shall have to give the preference to such an apparatus as will admit—

1. Of an easy collection and accurate measurement of the sample.
2. Of an easy application of the respective re-agents and accurate measurements subsequently.
3. Of repeated of the same quantity of re-agent for same length of time.

Among the numerous methods proposed and apparatus constructed for technical gas analysis, those of Walthar Hempel claim precedence as being accurate, rapid, and almost universally applicable. By way of qualifying this assertion, I may say that Hempel's apparatus has the following advantages:—

1. It admits of the use of all sorts of solid or liquid re-agents, including such absorbing agents as fuming

$\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ , bromine, etc., which destroy India-rubber joints, or attack the grease used for lubricating glass stopcocks.

2. It allows of a complete exhaustion or utilisation of the re-agents, including such re-agents as pyrogallol,  $\text{Cu}_2\text{Cl}_2$ , etc., which are spoiled by contact with air.

3. It greatly obviates the errors due to the mechanical absorption of gas by the absorbing agents, and finally, it can be used for the analysis of mixtures of  $\text{N}$ ,  $\text{H}$ , and  $\text{CH}_4$ , giving results which are sufficiently accurate for technical purposes.

I will now, after these few introductory remarks, endeavour to describe the various parts of Hempel's apparatus, and explain their respective uses.

First of all, we have the apparatus used for the collection and measurement of the sample of gas to be tested. This consists of a couple of gas burettes A and B (see Fig. 1), communicating with one another

FIG. 1.

by an India-rubber tube. One of the burettes—the one in which the gas is collected and measured—terminates in a short capillary tube, fitted with a short piece of India-rubber tubing which can be closed by means of a pinchcock *d*. The burette B is divided into 100cc. Now, if we want to collect and measure a certain sample of gas, we proceed as follows: Both burettes A and B are completely filled with water, care being taken that all the air contained in the India-rubber tube connecting the burettes is displaced, which may readily be done by raising A, B being closed at the time, and shaking the apparatus, when

any bubbles of air retained in the India-rubber tube will ascend and escape through A. As soon as the apparatus is properly filled with water, *d* is closed by means of a pinchcock, and the greater part of the water in A poured out, the connection between the two burettes being shut off by pressing the India-rubber tube while this is being done, so as to prevent any air getting into B. We now connect B by means of a suitable tube with the apparatus from which the gas is to be drawn; open *d*, and, by lowering A, syphon the gas into the measuring tube. As soon as a sufficient quantity has been collected, *d* is closed, and the apparatus allowed to stand for a minute, so as to allow the water to flow down from the sides of the tube. We then equalise the pressure in A and B by raising or else lowering A, as the case may be, till the columns of water in both tubes are exactly on

FIG. 2.

a level, and then read off. It is convenient to measure out exactly 100cc. of gas, the results obtained by subsequent absorption, etc., then at once represent the percentage. In order to obviate the error due to the mechanical absorption of gases by water, it is well to employ water previously saturated with the gas to be tested. All the measurements, it is almost needless to say, must, of course, be made at temperatures as nearly constant as possible. If we are dealing with a gas containing considerable quantities of constituents, which are decomposed by, or else very

soluble in, water, the above method cannot, of course, be used. In such a case we may use another form of burette, very similar to the gas burette originally designed by Winkler (Fig. 2). It differs from the simple gas burette only by the measuring tube B being fitted with two glass stopcocks *c* and *d*; the stopcock *c* is a three-way cock, by means of which the measuring tube B can be shut off from, or set in, communication with the second tube A, or else the air outside, or a pump. The collection and measurement of samples by means of this burette is done in the following manner: The measuring tube B is thoroughly dried by drawing a current of dry air through it, communication with A being shut off by means of the three-way cock. By means of a suitable tube attached to *c*, and connected with the apparatus or space from which the gas is to be taken, the gas is drawn through the measuring tube (this is easily done by a small pump or aspirator attached to the three-way cock *c*) till all the air has been displaced by the gas, when *c* and *d* are turned, so as to shut off the gas in B from the air outside, as well as from communication with A. Water is then poured into A, and by turning *c* can be gradually admitted into B, so as to absorb the soluble constituents. When the absorption is completed, the residual volume of gas is read off, the difference between this and the original volume (100cc., since B holds exactly 100cc. when full) directly giving the percentage of soluble gases.

So much for the modes of measurements by means of Hempel's gas burette, and we have next to consider the apparatus employed for the subsequent treatment of the sample—viz., the absorption of its respective constituents. Hempel used for this purpose two apparatus, which he terms the simple and the compound absorption pipette. The simple absorption pipette (Fig. 3) essentially consists of two glass bulbs *a* and *b*,

FIG. 3.

FIG. 4.

connected by means of the bent glass tube *d*. (N.B. The Fig. also contains a small third bulb *c*, which, however, is not strictly required; most of the simple absorption pipettes, in fact, only consist of the two bulbs *a* and *b*.) The lower bulb *b* is connected with a capillary U-tube *u*, fixed on a white porcelain plate *mm*; the whole apparatus is mounted on a suitable wooden stand. The absorbing agent is introduced into *b*, which must be completely filled with the solution, whilst the second bulb *a* remains nearly empty. A slight modification of the simple pipette is shown in Fig. 4. It is intended for the use of solid re-agents such as phosphorus, and merely differs from the ordinary burette just described, by that the second bulb *b* is made more of cylindrical shape, and has an opening at the bottom *k* communicating with an

aperture *l* in the stand, through which the solid re-agent can be introduced. The apparatus shown in the Fig. represents such a pipette filled with a solution of KHO and containing plugs of wire gauze, so as to obtain a large active surface on displacing the KHO solution by the gas to be tested; it is used for the estimation of CO<sub>2</sub>.

When an absorption has to be made by means of the simple absorption pipette, say with the KOH pipette represented in Fig. 5, the capillary U-tube is connected with the measuring burette containing the sample by means of a small capillary glass tube *f*, the pinchcock *d* opened, and by gradually raising A the gas is driven over from B into the bulb *b* of the pipette, where it displaces a portion of the absorbing fluid

FIG. 5.

which rises into the empty bulb. As soon as all the gas has been transferred, the connection with B is shut off at *i* (by means of a pinchcock), and the absorption in the pipette hastened by shaking the gas with the re-agent. When the absorption is complete, the communication with B is restored, and by lowering A the gas is syphoned back into the tube B, the pinchcock *d* closed, and the volume measured in the manner already described.

The compound gas pipette (Fig. 6) is intended for the use of re-agents which are acted upon by atmospheric air; it may be regarded as a combination of two simple pipettes, and consists of four bulbs, *a*, *b*, *c*, *d*, communicating by glass tubes. The first of these

bulbs (*a*) is again completely filled with the re-agent, *f* inst., an alkaline solution of pyrogallic acid; the second (*b*) is empty; and the third bulb (*c*) is filled with distilled water; and the fourth, again, is empty. When an absorption has to be made, bulb *a* is connected with the measuring burette in the manner already mentioned (see Fig. 5) and the gas passed in. The liquid displaced in *a* then rises into the second bulb *b*, and the air displaced in this is forced into the third bulb *c*, where it displaces an equal volume of the distilled water, which then rises into the fourth and last bulb *d*. Thus we see that the displaced absorbing agent in this pipette only comes into contact with the small quantity of air contained in *b*; now since the communication of *b* with the atmosphere is shut off by

FIG. 6.

the water in the third bulb *c*, the action of the small quantity of air or oxygen in *b* upon the re-agent soon ceases; the oxygen is absorbed, and there remains a perfectly indifferent gas—viz., nitrogen. The compound gas pipette is used for the absorption of oxygen by alkaline pyrogallic acid solution or of  $\text{CO}$ , by an ammoniacal solution of  $\text{Cu}_2\text{Cl}_2$  (cuprous chloride) re-agents, which must not, of course, be exposed to air—viz., oxygen.

The combustion or explosion of gases is also carried out by means of a gas pipette, which is represented in Fig. 7. The bulb *b*, in which the combustion is effected, is rather thicker in the glass than the bulb

FIG. 7.

of the ordinary gas pipette, and has two platinum wires fused into the top *m*, through which an electric spark can be passed. The communication with the second bulb *a* can be shut off at pleasure by means of a glass stopcock *d*. The first bulb *b* is completely filled with a dilute solution of  $\text{KHO}$ ; *a* is empty. The gas to be exploded is introduced by means of the

gas burette in the usual manner, the requisite quantity of air and hydrogen added, and after closing *d* and *c*, and mixing the gases thoroughly by shaking, the mixture is exploded by passing a spark through *m*. On opening *d* some of the liquid rises in the bulb *b* proportionally to the contraction produced by the combustion. The residual gas is then syphoned back into the burette and measured. The air required for such an explosion is of course accurately measured, and introduced by means of the burette, and so is the hydrogen. The latter is generated in a separate simple gas pipette (Fig. 8) by means of pure zinc and dilute sulphuric acid. The zinc is used in the form of a hollow stick *d*, which is fixed on a glass rod *r*, passed through a cork, and is thus introduced into the bulb *b* of the pipette, which is then completely filled with dilute  $\text{H}_2\text{SO}_4$ . The evolution of hydrogen at once commences, and *e* being closed the hydrogen evolved in bulb *b* displaces the acid, forcing it up into bulb *a*, till it is no longer in contact with the zinc, when the evolution ceases. On opening *e* the hydrogen in *b* is driven out by the pressure of the acid in *a*, which again descends into the first bulb, where it

FIG. 8.

comes into contact with the zinc, and setting up a brisk evolution of hydrogen, but as soon as *e* is again closed, the acid is forced back into *a*, and the evolution stops. Thus we have in this hydrogen pipette a means of generating a continuous current of hydrogen, sufficiently pure for combustion or explosion. Regarding the chemical principles involved in the process of burning or exploding gases, and the various precautions to be observed, I must refer to the chapter in Bunsen's "Gasometry" (translated by H. E. Roscoe), as such a discussion is altogether beyond the scope of this sketch.

In order to illustrate the working of the whole apparatus, it will be well to consider the analysis of a mixture containing most or all of the gases likely to be met with in actual testing. Let us take a mixture of  $\text{CO}_2$ ,  $\text{O}$ ,  $\text{CO}$ , olefines (viz.,  $\text{C}_2\text{H}_4$ , etc.),  $\text{CH}_4$ ,  $\text{H}$  and  $\text{N}$ . A sample of this gas—say 100 c.c.m.—is collected and measured in the gas burette. We next absorb the  $\text{CO}_2$  by passing the gas into an absorption pipette, containing a solution of 1 part of  $\text{KHO}$  in 2 parts of water (Fig. 4). To ensure a rapid and complete absorption the bulb *b* containing the caustic potash is partly filled with plugs of wire gauze, which on displacement of the potash solution by the gas offer a large surface moistened with the re-agent. The absorption of the  $\text{CO}_2$  is almost instantaneous—all we have to do is to pass the gas into the apparatus and syphon it back

again to be measured. The contraction produced directly gives us the percentage of  $\text{CO}_2$ , since we started with 100cc. The remaining gas contains O, CO, H,  $\text{C}_2\text{H}_4$ ,  $\text{CH}_4$ , N; we next absorb the oxygen. This may be effected in two ways—by means of moist phosphorus or by an alkaline solution of pyrogallous acid. The former method is by far the more elegant of the two, but not universally applicable. The absorption is done in an ordinary pipette (Fig. 9), the bulb (b) of which is filled with thin sticks of yellow phosphorus surrounded by water. The gas to be tested is introduced in the usual manner, and by displacing the water in b comes into contact with the moist surface of the phosphorus which speedily absorbs all the oxygen from it. The absorption proceeds best at about  $15-20^\circ\text{C}$ ., and is complete in ten minutes. The small quantity of phosphorus acid formed by the absorption dissolves in the water present, and thus the surface of the phosphorus always remains bright and active. As has already been men-

or else with the KOH pipette, which in this case, of course, simply serves as a kind of receiver. Finally the gas is syphoned back into the burette and measured—two-thirds of the contraction correspond to the amount of H originally present in the mixture of gas and air. The  $\text{CH}_4$  is not attacked by sulphuric acid (ordinary 30 per cent.  $\text{SO}_3$ , Nordhausen acid answers well enough). The acid is contained in an ordinary absorption pipette (Fig. 10), the small bulb c of which is filled with pieces of broken glass or glass wool, so as to offer a larger absorbing surface to the gas. The absorption is complete in a few minutes, but the remaining gas previous to measuring should be passed into the KOH pipette and back again, so as to free it from fumes of  $\text{SO}_3$ . Residual gas: CO,  $\text{CH}_4$ , H, N. The carbonic oxide is next absorbed by means of an ammoniacal solution of cuprous chloride in a compound absorption pipette. The gas has to be shaken with the absorbent for about three minutes. It must be borne in mind that  $\text{Cu}_2\text{Cl}_2$  solution also absorbs

FIG. 9.

FIG. A.

FIG. 10.

tioned, this neat and accurate method is not universally applicable; the following are the conditions under which it can be used:—The percentage of oxygen in the gas must not be more than 50%, and the gas must be free from ammonia,  $\text{C}_2\text{H}_4$  and other hydrocarbons, vapour of alcohol, ether and essential oils. In the instance we have chosen, the phosphorus method would hence not be applicable, as our mixture contains  $\text{C}_2\text{H}_4$ . We must therefore resort to the second method using pyrogallous acid. The absorption is carried out in the compound absorption pipette (Fig. 6), the bulb b of which is completely filled with an alkaline solution of pyrogallous acid made by dissolving 1 part (by volume) of a 25 per cent. pyrogallous acid solution in 6 parts of a 60 per cent. solution of caustic potash. The absorption is complete in about five minutes, but may be hastened by shaking. The remainder  $\text{C}_2\text{H}_4$ , CO,  $\text{CH}_4$ , H, N of our gas now contains N, and the next step is to absorb the  $\text{C}_2\text{H}_4$ , which is done by means of fuming, and determine the  $\text{CH}_4$  by explosion. Let us choose the latter method and take a portion, say a-half, of our residual gas for the estimation of hydrogen. The absorption of the hydrogen is based on the fact that palladium in a finely divided state so-called palladium black—is capable of completely burning hydrogen when mixed with excess of air, and slowly passed over the metal at the ordinary temperature. About 13gm. of palladium black are placed in a small U-tube (Fig. A) plunged into cold water, and the gas mixed with an excess of air (which of course must be accurately measured) is passed slowly through the tube two or three times, the tube at the time being connected with an ordinary absorption pipette filled with water

oxygen, and, according to Hempel, considerable quantities of  $\text{C}_2\text{H}_4$ , hence these gases must be removed previously. Residue:  $\text{CH}_4$ , H, N. We may now either determine both  $\text{CH}_4$  and H by exploding with an excess of air in the explosion pipette and measuring (1) the contraction produced, and (2) the amount of  $\text{CO}_2$  formed (by means of the KOH pipette); or we may, according to Hempel, absorb the hydrogen first of all in this reaction—provided the U-tube be kept well cooled with water. At about  $200^\circ\text{C}$ ., however, a mixture of air and  $\text{CH}_4$  is also acted upon by palladium. The presence of CO, vapours of alcohol, benzene and hydrochloric acid interferes with the absorption by palladium.

The palladium can be used for many consecutive experiments, but must be kept as dry as possible. After it has been used for several absorptions it may be regenerated by plunging the tube into hot water and passing a current of dry air through it.

Having estimated the hydrogen, we have lastly to determine the  $\text{CH}_4$  in the remainder of our gas. This contains  $\text{CH}_4\text{N}$  and H, the amount of the latter being known from the previous experiment. The gas is mixed with the requisite quantity of air and hydrogen, introduced into the explosion pipette and fired by means of a spark. The water resulting from the combustion condenses in the bulb of the pipette, whilst the  $\text{CO}_2$  formed is absorbed by the KOH solution present. Hence the total contraction produced corresponds to:

- The hydrogen present in the original gas +  $\frac{1}{2}$  its vol. of O (the quantity requisite for complete combustion).
- The known quantity of hydrogen added +  $\frac{1}{2}$  its vol. of O.

c. The  $\text{CH}_4$  present + 2 vols. of O requisite for its combustion.

Since  $a$  and  $b$  are known, or can be readily calculated from the previous data, we can by subtracting  $(a+b)$  from the total contraction obtain  $C-(a+b)=c$  contraction due to  $\text{CH}_4$  alone, and one-third of this is equal to the volume of  $\text{CH}_4$  present, as will be readily seen from the above equation.

The remaining nitrogen is estimated by difference, a direct method of determination not being known at the present time.

The above brief sketch will at all events suffice to show the value of Hempel's methods for technical purposes. A complete analysis of a complex mixture like the one chosen for the purpose of illustrating these methods need only occupy twenty to thirty minutes, so that a great number of such analyses may be carried out in a day. Moreover, with due care and skill, the results obtained are very accurate indeed; in fact, more accurate than is generally required or expected from a technical process.

#### DISCUSSION.

Dr. HEWITT: We are greatly indebted to Dr. Bott for his valuable paper. All I can say is, if we have not thoroughly grasped all he wished to convey in his demonstrations with the apparatus, he has nevertheless reduced a very complex system of testing gas to a very simple operation, and I certainly think that syphoning back must give a degree of accuracy which is not otherwise attainable. We know that there are many processes which require continual testing for their elucidation. It is not merely necessary to know what may be done in the course of 24 hours, but it is absolutely necessary to know what is going on from time to time. I am sure that Dr. Bott's method would be valuable in making the tests of gases in the working of Deacon's process for the manufacture of chlorine. Difficulties often arise in the analysis of mixed gases, and I should like to have had the opportunity of having the mixed gases in Deacon's process determined by some simple method like the one before us. I have no doubt, from what I have seen to-night, that possibly this apparatus might be of considerable assistance in facilitating the rapid determination of the carbonic acid and hydrochloric acid which abnormally are found in the gases passing to the bleaching powder chambers, and which, when present in any appreciable quantity, defeat the manufacture of good bleaching powder.

Dr. MARKEL: I have had some experience with the apparatus before us, and would therefore like to add, as regards its accuracy, that on comparing it with Bunsen's method I found the results obtained agreed within 0.1 to 0.3 per cent. for each gas. The gas analysed on this occasion contained  $\text{CO}_2$ , O, Co, H,  $\text{CH}_4$ , N. Besides showing this surprising degree of accuracy, Hempel's method is the most expeditious of any I know. I have made as many as fourteen analyses daily with it. Dr. Bott has remarked that it is necessary to allow the gas to stand for a few minutes in contact with the first reagent. I do not think it is necessary to let the gas remain longer in contact with the potash than is required to pass it into the pipette and back again into the burette, when the  $\text{CO}_2$  is completely absorbed. The O is absorbed by the alkaline pyrogallol in two to three minutes. Phosphorus is preferable for absorbing the oxygen, but as the above-mentioned gas contained

traces of ammonia, it could not be used. Co is also completely absorbed in the pipette fitted with ammoniacal cuprous chloride in two to three minutes, provided the pipette is well shaken. The palladium-black causes union of the H and O, when the gas is allowed only to pass once over it and back again. It can be used for an indefinite number of times, provided the water which collects in the tube is removed from time to time by allowing warm air to pass over it. The whole operation ought not to exceed half an hour if everything is well prepared.

### Liverpool Section.

Notices of papers and communications for the meetings to be sent to the Local Secretary.

The next meeting of this Section will be held at University College, Ashton Street, April 1, 1885, when the following will be the order of proceedings:—(1) Election of Officers for Session 1885-86. (2) Discussion on Mr. Pratt's Paper, read March 1. (3) Paper on Electric Lighting, by Mr. Holmes.

UNIVERSITY COLLEGE, ASHTON STREET, LIVERPOOL,  
Wednesday, March 4, 1885.

MR. E. K. MUSPRATT IN THE CHAIR.

#### "THE RIVERS POLLUTION BILL."

BY E. K. MUSPRATT.

As one of the most useful functions of our Society is to take into consideration, and to criticise with the knowledge of experts, any proposed legislation of the character of the "Rivers Pollution Bill," I have at the request of the Committee prepared a paper on the subject.

I must, however, take this early opportunity of saying that I am by no means competent to deal in a comprehensive manner with this most difficult subject, and that I have undertaken the task solely with the view of raising a discussion on the Bill by members more competent than myself.

The growth of manufacturing industry, together with its manifold blessings and the consequent increase of the well-being of the people, is unfortunately accompanied by evils which it is our duty, and I hope our desire, to mitigate. The framers of this Bill, I am afraid, either from ignorance or with design, attempt by law absolutely to prevent them. From my reading of the Bill there is no clause similar to the clause in the Act of 1876, which exempted the manufacturer from the penalties of the Act, if he used the best practicable means for rendering harmless the polluting liquid which he sent into a stream. It follows, therefore, if this Bill becomes law, that unless he can purify the liquids flowing from his works, so as to satisfy the standards prescribed by the Bill, a manufacturer must absolutely close his works, and sacrifice all the capital invested therein. As all of you have read the proceedings of the London Section, in which Mr. Cresswell gave a very able exposition of the Bill, it will be unnecessary for me to attempt to call your attention at any length to the legal aspects of the question. Mr. Cresswell says the Act of 1876 was "a piece of lame and impotent legislation," and this Bill is brought in to remedy its defects. Now, the prime defect of that Act, he says, is the want

of machinery for carrying it into execution, and he points to the reluctance of the sanitary authorities (the greatest culprits themselves) to put the Act into execution, but admits that recourse may be had to the Local Government Board, to compel the sanitary authorities to put the Act in force.

He then complains of the delay caused by the visit of the inspector, who really has to determine upon the best practicable means to prevent the pollution. This, then, is the grievance, and this Act is intended to remove it, which it proposes to do very effectually by prohibiting the running of any polluting liquid into any stream or river, whether tidal or otherwise, irrespective of cost to the miner or manufacturer.

I think, however, the case against the Act of 1876 has not been made out. Mr. Cresswell says fifty-three proceedings have been taken under the Act, and *twenty-four orders* to restrain pollution have been obtained, but have never been enforced at all.

Now, why have these orders never been enforced? I applied to Mr. Cresswell for an explanation, and he wrote to me to say, "that it is not the duty of the Local Government Board to enforce them; on the contrary, they have in almost every case intervened to extend the period assigned for compliance with the order under Clause 3 of the Act of 1876, and that, *e.g.*, the order in the Hereford case, which was made in 1878, has been suspended in successive years until February, 1885." But by this Clause 3 the Local Government Board can only grant this extension of time if they are satisfied, after local inquiry, that further time ought to be granted to enable the sanitary authorities to adopt the best practicable and available means for rendering harmless the sewage matter complained of.

Now as Mr. Cresswell admits that in some cases the Act has been put in force, it seems to me that in this Hereford case it is probable no available means are at hand, although, as we are aware, there are several towns which, to a great extent, do render their sewage harmless, it seems strange that nothing has been found practicable—in this special case—for seven consecutive years.

In the case of manufacturing pollutions, the difficulty may be greater, and the cost to the individual manufacturer may be so great and so much out of proportion to the necessity of the case, that the Local Government Board would be fully justified in stopping proceedings on the ground that "some material injury will be inflicted by such proceedings in the interests of such industry."

But is it not possible, without altering the intention of the Act, to improve its machinery? We are all agreed that pollution of rivers should be prevented, provided the cost of such prevention is not too great, and if the present Act is as faulty as it is said to be, something should be done to amend it.

If we attempt to march too fast we may very easily frustrate the object we have in view, and it is desirable, in the first instance, to ascertain what is practicable in the way of prevention. We know how the Royal Commissioners, at the instigation of Dr. Frankland, decided that certain standards of purity were attainable, and these standards are practically adopted in the Bill we are considering.

It was a fatal error that on the Commission only theoretical chemistry was represented in the person of Dr. Frankland, for I need hardly remind members of our Society that something beyond a knowledge of scientific chemistry is required to decide what is practicable in chemical operations on a large scale. But even scientific chemists are by no means unanimous in favour of the standards recommended.

Mr. Crookes is of opinion they are on an entirely erroneous basis, and I think we must all agree with

him that to lay down absolute standards of purity for every river was a mistake.

It certainly seems more reasonable that each river should be considered on its merits. The addition of certain substances which by themselves might pollute a pure stream, would be beneficial in the case of the Irwell or the Mersey, and until sewage matter is kept out of the Thames the addition of salts of iron, manganese, zinc, or bleaching liquor, for example, need not be prohibited. It is straining at a gnat and swallowing a camel if, before we have dealt effectually with the great sewage question, we press on chemical manufacturers enormous expense in order to improve the quality of the liquids escaping from their works.

If the germ theory of the origin of cholera and typhoid be true, it is far more important in a river like the Thames, which is a source of potable water, to prevent its pollution by sewage than by manufacturers' refuse, and yet, so far as I know, this has not yet been accomplished.

It is true Sir John Lawes seems of opinion that the sewage of London itself is of great benefit in increasing the catch of fish in the Channel, but the inhabitants of London ought not to be obliged to drink the sewage of the population above the intake of the water companies, and if pollution of this character can be prevented there would be no reason against enforcing the adoption of similar means of purification in towns on other streams. Whether the standards recommended by Dr. Frankland are attainable or not, some standard for sewage pollution might certainly be found after practical experience in dealing with the sewage on a large scale, and such standards might fairly be made more stringent as the methods of purification improved. What is really wanted is a practical method of dealing with sewage on a large scale, and the experience of the last ten years ought to be able to furnish us with one.

What might fairly be required of an inland town ought not to be required for a town on an estuary like the Mersey, and the same principle—*i.e.*, having regard to the general character of the river—should be applicable to pollution from manufacturing processes. I am therefore of opinion that Mr. Crookes is clearly on the right path in making the river or stream, and the uses to which it is to be applied, the standard of pollution, and not the liquid running into it.

The criticisms of the manufacturers when the standards of the Pollution of Rivers Commission were first published are in the main applicable to those in the present Bill.

[Mr. Muspratt here read extracts from the evidence of Mr. Stevenson and others before the Royal Commission.]

As regards solid matter, Mr. Newlands pointed out at the London meeting that the great bulk of the rivers of the kingdom contained more than the standard as suspended mud, and that the colour standard in subsection C was far too stringent, and really is of no use, for many natural rivers or streams are much more coloured.

Mr. Johnson complained in London that in some cases they were too stringent and in others too lax, particularly those referring to acidity and alkalinity, if they were permitted in any stream employed subsequently as a water supply.

In many cases these standards are absolutely impracticable, and Lord Salisbury, in introducing the Bill of 1875, admirably summed up the objections to them: "The difficulty that was felt with regard to these tests was that they struck too far, and that on the one hand they would include water flowing from perfectly innocent sources, while on the other hand they were not sufficiently stringent to affect the

very nuisances against which the legislation was directed."

After giving this Bill my best consideration, I have come to the conclusion that it is framed on an entirely wrong principle, inasmuch as it proposes the same standards of pollution irrespective of the locality and circumstances of the case.

If passed into law, it would have a most injurious effect on the industry of the country, as many works and mines could not possibly comply with its provisions. If the present Act cannot be enforced on account of the power given to the Local Government Board to supervise or restrain its application, the attempt to give this power to individuals, or even to induce individuals to complain of pollution by paying the penalties for the offence to them, as it is suggested in Clause 3, might be grossly abused for private purposes.

The power to set the Act in motion ought to rest with a public body, and if the sanitary authorities are interested parties, the new County Boards, which are sure to be established at an early date, seem to be the proper body for the conservancy of the rivers in their district, and the preservation of the rivers from pollution.

The attempt to fix standards of universal application is wrong in principle, but after some experience local standards on the lines of Mr. Crookes' suggestion—viz., that the river itself should be the standard of purity, and that no liquid should be allowed to be sent into a river if the liquid contains a greater percentage of impurity than the river itself—might possibly be adopted.

I have in the foregoing pointed out how injurious to manufacturing interests this Bill might become, if made law, but have not attempted to go into any minute details on the chemistry of the question, which I know will be ably handled by other members present.

Dr. Hurter has informed me of some investigations in Saxony which bear out the view I have taken, that until the sewage question is dealt with, the keeping-out of manufacturing refuse, except solid matter, which may interfere with the flow of a stream, is hardly necessary.

Metallic salts disappear from solution in a marvellous manner, and cannot be traced at even a short distance from the place where they flow into a stream. These same investigations will also support the view that regard must be had to the condition of the river itself, both as to its velocity and the volume of water; and I have no doubt the discussion this evening will throw further light upon many of the points I have so lightly touched upon.

The subject has now been discussed in most of our sections, and the result will be to give the Council of the Society ample information to guide them in any suggestions they may have to make to those in authority, on this Bill or any other that may be brought in to deal with this most important question.

#### DISCUSSION.

Dr. HEWITT thought it was clear upon the evidence before the Rivers Pollution Commission, that sewage pollution and trades pollution stood upon a totally different footing. The sanitary objection had arisen not from trades pollution, but from sewage pollution. He thought it would be a new feature in English law if simply for aesthetic reasons Parliament were to interfere with those industries by which England had gained her greatness. The greater evil undoubtedly was sewage pollution, and in many instances it interfered seriously with the health of towns. That this was a very difficult question no one would deny, especially when he heard the enormous cost to Salford of their sewage system.

While the sanitary authorities are the chief sinners, they are constituted the authority to carry out the law and put pressure upon the manufacturers, but they had found practical difficulties in dealing with the question. The chairman of the Conservancy Committee in Salford acknowledged that the more he tackled the question the more the mountain of difficulty seemed to grow, and he found that it was not a question to be gone into lightly, or that very strict standards could be employed. Dr. Hewitt held that something should be done, but whatever was done, it should be carried out in a uniform manner. The only point upon which he (Dr. Hewitt) was inclined to differ from their Chairman was as to the estuaries. There was a great difference in estuaries, and some distinction should be made between one estuary and another. They must not introduce a system which would bear more hardly upon one manufacturer than another. They must not press upon the one higher up the river, and leave the one lower down to escape altogether. If so, this would introduce between men in the same trade a very objectionable want of uniformity. He would support almost any degree of strictness in a Noxious Vapours Bill, because it was required from all manufacturers in the same trade to conform to the same standard. It was abundantly clear that sewage effluents could never be fit for potable water, and, therefore, there was no need to seek for such a standard of purity from the manufacturer; it was idle to expect that the standards in this Bill could be realised, for natural sources of pollution would often make the river to infringe such standards. If they passed an Act of Parliament which could not be realised, there would be absolutely no results from it, whereas if they could pass an Act of Parliament which could be carried out by some conservancy board or county board, working under the Local Government Board, some good might be effected. If a river was an important source of food supply, then it was very important to take steps to prevent its serious pollution, but the case was different when the rivers were used for drainage and trade purposes alone. The Mersey and the Irwell had ceased entirely to be sources of food, and to insist upon the same standard in reference to these rivers, as for those other rivers to which he had referred, would, in his mind, be to inflict a lasting injury upon trade in which the interest of this country was so largely bound up. He therefore thought the Legislature would hesitate to pass such a Bill. It had been proposed that instead of sending the waste water from manufactories into the rivers it should be sent into the sewers. The men who owned large works were those who paid the large rates, and nobody had a better right to use the sewers than those who so largely paid for them, and if this user of the sewers caused any damage the manufacturer should be made liable for it. At the same time he admitted some little pressure should be brought to bear on the manufacturers, as they were quite ready to blame each other and do nothing. Any one reading the replies to the inquiries addressed by the Rivers Pollution Commissioners could see that each manufacturer was impressed with the value of good influx water, and was ready to apportion its value in money, but was very silent about the effluent, or held that nothing could be done. An Act might be passed which placed rivers under inspection, and required "the best practicable means" to be adopted, and if such a measure was put in force uniformly, fairly, and gradually all over the kingdom, due regard being had to difference in the value of rivers as sources of potable water, food supply, etc., then some very considerable improvement might in time be brought about.

Professor J. CAMPBELL BROWN said: In this matter

there were two opposing interests; on the one side there was the interest of the manufacturer and the public who used his products. Every one would agree that our manufactures ought not to be needlessly hampered; and most people would agree that they must not be altogether stopped, even if some of our rivers had to be spoilt, and they ought not to forget the interest of future manufacturers, although that might have little weight compared with that of those already established. On the other side there was the interest of the riparian owners, the riparian tenant-farmers, and all those various interests that were represented by conservancy boards, including the people who fish in the streams, whether for food or for sport. The object of legislation ought to be to give the maximum of freedom to each side, with the minimum of interference with the other. This being the case, he did not think he could altogether agree with Mr. Muspratt, when he said that no legislation ought to interfere with the impurities cast into the stream by manufacturers until after sewage was dealt with, because although no doubt large quantities of sewage impurities cast into a stream were very prejudicial to health in every way, still the introduction of moderate quantities of sewage did not interfere with the fish, did not interfere with the farmer, did not injure his cattle, although it rendered the river useless for domestic purposes. But the introduction of effluent water from some factories would destroy the river for any useful purposes, except for carrying certain refuse materials into the sea. For instance, paper makers could keep out of the rivers nearly the whole of the poisonous esparto resin, and they might also keep out the largest portion of the fibrous matter, and after recovering most of their alkali, they might neutralise the remainder by some of the acid which they used for bleaching purposes, and then the effluent water would not destroy the fish. He thought every reasonable man would agree that the paper makers, for instance, ought to be compelled to bring their effluent water up to that standard of purity. In some other cases he thought it was very likely that legislative powers could not be put in force with any degree of stringency, without great hardship. He did not see any other way out of the difficulty than by agreeing that there should be different standards for different streams. There might be some streams devoted to manufactures, and others devoted to the riparian owners and the tenants. He entirely agreed with Mr. Muspratt in all he said with regard to standards, and he did not think that they could fix standards which should be applicable to all rivers, and which it would be just or convenient to make compulsory through the whole country. It was utterly impossible, and he did not think it was at all necessary or desirable. If standards could be agreed upon, they would no doubt greatly assist the inspector; they would define his work, and by a chemical analysis he would be able to prove his case easily in a court of law. But an Act of Parliament should be for the benefit not of the inspector only but of the whole nation. Every stream should be treated on its own merits, taking into consideration its condition before the effluent water passed into it, and the use made of the river below, and also the importance of the manufacture, and the possibility of purifying the effluent water at a reasonable cost. If it did cost the manufacturer some money he ought to be called upon to bear it for the good of the public. Where it would be ruinous to an important manufacture to purify the effluent water, such manufacture should be allowed to flourish only on certain rivers which were not reserved for fish and for other purposes.

Mr. SINCLAIR pointed out that the Bill had been brought in by three private members and not by the Government, and he thought it would be utterly impossible to get the Bill into a shape that would be acceptable, and it ought to be opposed until it was preceded by a General River Conservancy Bill brought in on the responsibility of the Government. Looking at his notes on the old Bill of 1873, he found that some of the most objectionable tests which were struck out of that Bill by the Committee of the House of Lords, to whom it was referred, were reintroduced in the present Bill. When the rivers pollution question was dealt with they should take care that no proceedings were taken except with the sanction of the Local Government Board, and that nothing should be required from the manufacturer that was not reasonably practicable, and that he should not be subject to prosecution when he kept within the prescribed tests. The Local Government Board should make more use of the power they had to make local sanitary authorities do their duty. He made this remark, because the Local Government Board did not exercise the power they now had in their hands.

Mr. HENRY BRUNNER could not agree with that clause in the Bill by which any aggrieved individual could compel the sanitary authority to take proceedings. He thought the authority which made the law ought to have the power of enforcing it and the responsibility for its being carried out. At present if a man could prove injury, he had his remedy at common law, but it was the cost of obtaining that remedy that deterred people, and thus rivers continued to be polluted. Under the Bill as proposed, a great amount of vexatious litigation would arise. He doubted whether county boards would form a proper authority for dealing with this matter, and should prefer one central authority. He thought the question of fixed standards extremely objectionable, and not likely to attain the desired object, as they would enable either sanitary authorities or manufacturers, so long as they were within the standard, to turn into a pure stream matter which would nevertheless pollute it, and although some of our rivers were little better than common sewers, it was desirable that some at least of the others should be kept as pure as possible. Though he was of opinion that pollution by sewage matter most of all required consideration and attention, he did not think that the prevention of river pollution was specially directed against the manufacturing interests of the nation. If the law said from the beginning that no sanitary authority or manufacturer should be allowed to turn into a stream matters of worse character or in greater quantity than the water of the stream already contained, and that the state of the stream itself should be the standard of purity for that stream, he believed that such a law would assist in the development rather than restrict the progress of manufacturing industry. But in Lancashire—probably elsewhere also—they had had instances where beautiful streams of pure water had been purposely polluted by manufacturers with the object of preventing their use by possible competitors. He thought that the true interests of manufacturers lay in preventing the pollution of rivers as far as possible, and certainly no individual or collection of individuals should have the right of so polluting a stream, whether for their own profit or convenience, that no one else could use it after them.

Dr. HERTER thought that the Bill met some of the objections raised by Dr. Hewitt by Clauses 7 and 8, which provided that existing rights should not be affected by the provisions of the Bill, but the exact meaning of those clauses could only be made out by

lawyers. As regards the standards of purity, Professor Mills, when discussing them at Glasgow, considered some of them not sufficiently stringent to preserve the life of fish. Now, it appeared to him (Dr. Hurter) that it was not required that fish should be able to live in the fluids discharged from works into the rivers, but only in the mixture of the polluting fluid with the river water. Dr. Hugo Fleck, an eminent German chemist, had lately published a small pamphlet on the pollution of rivers in Saxony, and from this little book Dr. Hurter gathered Dr. Fleck's opinion on the subject. Dr. Fleck thinks that we cannot expect anything from river water but that it shall be sufficiently clean for washing purposes. He considers a river as the natural drain of the river valley. Dr. Fleck thinks that in determining the permissible pollution regard must be paid to the amount of water passing through the cross section of the river and also to the velocity of the stream. He thinks it would be no use to forbid the industrial establishments to pollute a river so long as the much larger pollution from town sewage is not excluded, because the pollution from sewage is usually much the most serious. In many instances it was found that the polluting matter from factories reacted upon the polluting sewage matters so as to purify the river. Dr. Fleck sums up with the following words:—"If we regard the rivers in the first place as the natural drains of the valleys, then we shall have to renounce the maintenance of a large stock of fish in a river in all cases where a large population, with numerous industrial establishments, inhabit the river valley. No rules would ever be able to keep out of a river everything that might prove a disturbance to fish life, where a river was at the same time in the service of both domestic and industrial life. Very often the effluvia of industrial establishments were represented as the cause of the decrease of fish, without any regard to the fact that the sewage of dwelling-houses might often have its influences. It was proved that the water-worms (*naïda*), who were the greatest enemies of roe, were found in those deposits of mud which were rich in faecal matters. Wherever a river was in the service of manufactures it would be impossible to make rules of Parliament which would re-establish in the river a large stock of fish." Thus Dr. Fleck's opinion goes a long way towards making each river its own standard—i.e., towards the suggestion of the Chairman.

Mr. MUSPRATT, replying on the discussion, said he did not mean that county boards alone should be the authority, but what he meant was that if conservancy boards were appointed for different rivers, or drainage areas, the county boards should be represented on the conservancy boards. He agreed with Dr. Hewitt in the Local Government Board having supervising power. They must have a central authority to see that all interests throughout the country were equitably and properly dealt with. He also agreed that it was absolutely impossible to fix standards at present, but it might be possible after they had had a lengthened experience, and after investigation by the new boards, who might take the whole question into consideration. They would have to consider the interest of each locality, and the best practical means of dealing with the pollutions in that locality. Dr. Campbell Brown scarcely agreed with him that the sewage should be first dealt with; but after all, sewage was the greatest source of pollution, and even in an æsthetic point of view, they should have regard for the nose as well as the eye. He certainly thought more progress might have been made if proper inspectors had been appointed under the Act. They wanted to find out the best practical means of dealing with the sewage, having regard to

the reasonable cost. He thought the present Act gave ample power for dealing with pollutions. It insisted upon the best practical means being adopted for the prevention of pollution. He thought they were all agreed that this should be done. They did not want to continue the pollution, and he thought all that Dr. Brown said with regard to paper makers was perfectly just and right. Paper makers were like everyone else—bound to use the best possible means to prevent pollution. He thought the intention of the Act was strong enough, and it was only a question of carrying out that intention. He therefore proposed that that meeting of the Liverpool Section of the Society of Chemical Industry "was of opinion that the Rivers Pollution Bill of 1881 was inadequate to secure the objects of its promoters, and would be injurious to the interests of manufactures, and recommends its early consideration by the Council of the Society, with a view to such action as the interests of industrial chemistry might require."

Mr. CAREY seconded the motion, and it was carried unanimously.

### THE LOSS OF ALKALI OCCASIONED BY SULPHUROUS ACID IN THE LEBLANC PROCESS.

BY J. W. PRATT, F.C.S.

THE question indicated by the title of my paper relates to one of the last stages of the manufacture of alkali by the Leblanc method.

The sulphate of soda produced in the earlier stages of the manufacture has already been decomposed, and the resulting black-ash lixiviated to yield the soda in solution before the loss which I have attempted to trace is set up. Once the alkali is obtained in solution as vat liquor, it is only necessary, in order to procure the various solid soda ashes, etc., to subject it to evaporation and concentration. In English works the concentration of the vat liquor is usually effected by causing it to flow from the vessels in which it has been prepared and settled, into long open pans attached to the rear of the revolving or hand black-ash furnaces, where the flame and residual heat play freely over its surface.

As the evaporation progresses, monohydrated carbonate of soda or "salts" separates out and another, or "red liquor," remains. The salts are removed by fishing, and the "red liquor" is also run off from time to time.

Farther manipulation converts the "salts" into the purest form of commercial soda or carbonated ash, and the "red liquor," in which the original impurities of the vat liquor are concentrated, into caustic ash. But the initial concentration which leads to this subdivision of products, and to so large an amount of water being evaporated economically, is not without its attendant disadvantages. One of these is the introduction of foreign matters into the alkali through the agency of the fire gases, which consist essentially of carbonic acid and oxide, unburnt oxygen, and invariably a small proportion of sulphurous acid, due to the sulphur present in the fuel employed. It is with the action of this last gas, sulphurous acid, that my experiments have to deal. The other gases, excepting the action of the CO<sub>2</sub> on the causticity of the liquor, are inert or at any rate harmless. But sulphurous acid being easily absorbable by the alkaline solution, leads to the formation of sulphites or hyposulphites subsequently oxidised to sulphate, and the alkali thus neutralised is to all intents and purposes lost. This loss of alkali has been variously estimated. Weldon\* has estimated it at about 2 per

\* Journ. Soc. Chem. Ind., January, 1883.

cent., and Moorhouse\* at from 0.10 per cent. to 0.20 per cent. sulphur on the soda-ash made.

The figures given below, on which my estimate is based, are the results of experiments carried out at two independent works of the Runcorn Soap and Alkali Co., Limited, with the kind permission of the general manager, Mr. Charles Wigg. During two periods, some months apart, I had taken for me at each works average weekly samples of the coal used for firing the furnaces, and of the vat and red liquors, salts, carbonated and caustic ashes produced.

The workmen took small portions of each of the substances daily for a week, and these weekly average samples were then divided down and analysed. After analysis, the weight of the substances being known, and their ratio one to another having been previously calculated over long periods of production, all the required data were to hand.

The total alkali was estimated in each sample, likewise the sulphide, hyposulphite, and total sulphate after oxidation with hypochlorite, acidification and precipitation as barium sulphate. All the results are calculated on 100 of  $\text{Na}_2\text{O}$ , after deduction of the  $\text{Na}_2\text{O}$  existing as sulphide. The total iodine consumed in the titration of the solutions, after deduction of that due to the sulphide, is reported as hyposulphite, according to the method usually practised in alkali works laboratories. I have so reported it in order to avoid complication and possible error through the employment of not very reliable methods for the determination of sulphite, hyposulphite, sulphide, sulphate and total sulphate when existing together in one solution. This arrangement can only affect the relative amounts of sulphate of soda mechanically and chemically introduced in the preliminary experiments.

The analysis which follows is the average of several months, and will serve to show the general composition of the vat liquors dealt with:—

$\text{Na}_2\text{O}$	= 100
$\text{NaIO}$	= 26.75
$\text{Na}_2\text{S}$	= 2.87
$\text{Na}_2\text{S}_2\text{O}_3$	= 1.02
$\text{Na}_2\text{SO}_4$	= .58
Total $\text{Na}_2\text{SO}_4$ after oxidation	= 6.81
$\text{NaCl}$	= 10.16
$\text{Na}_4\text{Fe}(\text{CN})_6$	= .313
$\text{Na}_2\text{SiO}_3$	= .23
$\text{Na}_2\text{Al}_2\text{O}_4$	= 1.50
Iron	= 0.213

The fuel employed was almost entirely derived from one source, and hence does not present much divergence in composition. So far as the present subject is concerned, the only point of particular interest is the amount of volatile sulphur it contains, as that of course leads to the formation of the deleterious sulphurous acid in the fire gases. Its analysis gives:—

Fixed carbon	= 57.50
Volatile matter	= 29.25 = volatile sulphur 1.77
Ash	= 8.25
Moisture	= .50
	100.00

#### A. WORKS, OCTOBER, 1881.—No. 1 EXPERIMENT—INITIAL EVAPORATION.

The pan attached to the revolver in this works measures  $28 \times 8 \times 1.5$  feet, and contains 336 cubic feet liquor, exposing a surface of 224 square feet. "Salts" made=about 60 tons per week.

Total  $\text{Na}_2\text{O}$  dealt with=about 50 tons per week.  
120 firing coal to 100  $\text{Na}_2\text{O}$ .

Ratio  $\text{Na}_2\text{O}$  as "salts" to  $\text{Na}_2\text{O}$  as red liquor=1.5:1.

	Vat Liquor.	Red Liquor.	Salts.
$\text{Na}_2\text{S}$	= 1.89	= 5.15	= nil.
$\text{Na}_2\text{S}_2\text{O}_3$	= 1.32	= 5.60	= .57
Total $\text{Na}_2\text{SO}_4$	= 7.12	= 23.50	= 2.32

$$\frac{(23.8 \times 10) + (2.32 \times 60)}{100} = 7.12 = 3.79 \text{ increase of}$$

sulphate of soda on 100 of  $\text{Na}_2\text{O}$ . This figure will of course include the sulphate of soda mechanically carried over by the draught of the furnace through the revolver. The hyposulphite calculated on the above basis

$$\frac{(5.6 \times 10) + (0.57 \times 60)}{100} = 1.52 = 1.06 \text{ } \text{Na}_2\text{S}_2\text{O}_3$$

in 100 of Alkali. These results give the alkali neutralised and lost by sulphurous acid as being .41%  $\text{Na}_2\text{O}$ , and the increase in total sulphate

$$\text{Mechanically carried over} = 1.89\%$$

$$\text{Due to increase in } \text{Na}_2\text{S}_2\text{O}_3 = 1.90\%$$

$$\text{Increase in total } \text{Na}_2\text{SO}_4 = 3.79\%$$

#### A. WORKS.—No. 2 EXPERIMENT—JANUARY 11, 1883.

	Vat	Red	Salts.
$\text{Na}_2\text{S}$	= 2.526	= 5.57	= nil.
$\text{Na}_2\text{S}_2\text{O}_3$	= 1.310	= 1.43	= 0.8
Total $\text{Na}_2\text{SO}_4$	= 7.90	= 21.43	= 2.57

$$\frac{(21.43 \times 10) + (2.57 \times 60)}{100} = 7.90 = 2.21\% \text{ increase}$$

Increase in hypo=0.95%=0.372%  $\text{Na}_2\text{O}$  lost

$$\text{Na}_2\text{SO}_4 \text{ mechanically carried over} = .51\%$$

$$\text{Na}_2\text{SO}_4 \text{ due to increase in } \text{Na}_2\text{S}_2\text{O}_3 = 1.70\%$$

$$\text{Total } \text{Na}_2\text{SO}_4 = 2.21\%$$

As the "salts" are removed and roasted into carbonated ash, and the red liquors are evaporated to form caustic ash, in furnaces where top heat is in each case employed, a further exposure to sulphurous fire gas is involved before the alkali is finished. The figures below show the extent of this loss:—

#### A. WORKS.—100 $\text{Na}_2\text{O}$ .

	Salts to Furnace.	Finished Carbonated Ash.
$\text{Na}_2\text{S}$	= .913%	= .22
$\text{Na}_2\text{S}_2\text{O}_3$	= .330	= .375
Total $\text{Na}_2\text{SO}_4$	= 1.470	= 1.900

1.9-1.47=.43% increase of 'sulphate or a loss of .18%  $\text{Na}_2\text{O}$  on 100 of alkali.

	Red Liquor.	Caustic Ash 48%.
$\text{Na}_2\text{S}$	= 2.117	= .22
$\text{Na}_2\text{S}_2\text{O}_3$	= 5.605	= (Na <sub>2</sub> SO <sub>3</sub> ) 6.32
Total $\text{Na}_2\text{SO}_4$	= 20.813	= 21.61

$$.827\% \text{ increase of } \text{Na}_2\text{SO}_4 = .369\% \text{ } \text{Na}_2\text{O} \text{ lost.}$$

Taking the mean of the two first experiments, and proportioning the amounts of alkali lost in finishing the two ashes, we find the total loss of alkali and increase in sulphate of soda on 100 of  $\text{Na}_2\text{O}$  to be thus arranged:—

	$\text{Na}_2\text{O}$ lost.
$\text{Na}_2\text{SO}_4$ mechanically introduced	= 1.20%
" chemically introduced	= 1.80
" carb. ash (1.5) furnaces	= .258
" caustic ash (1.0) furnaces	= .331
Total introduced	= 3.589% = .617%

This finishes the experiments at Works A, and the figures which follow are those obtained at the much larger works of the two.

#### B. WORKS.—NOVEMBER, 1881.

The samples are average ones from pans attached to two revolvers.

The dimensions of the pans are  $46 \times 8 \times 2'$  and  $45 \times 6 \frac{1}{2} \times 2'$ , and they expose a joint area of 666 square feet to the flame, with a cubic capacity of 1332 cubic feet.

Salts made=about 170 tons per week.

\* Trans. Newcastle Chem. Soc., 1871.  
† Of this iron, 27% exists as sodium ferrocyanide, and 73% as ferrous-sodium sulphide,  $\text{Na}_2\text{FeS}_2$ , (H.L.O.).

Total  $\text{Na}_2\text{O}$  dealt with—about 130 tons per week.  
Coal—104 : 100  $\text{Na}_2\text{O}$ .

Ratio  $\text{Na}_2\text{O}$  as salts to  $\text{Na}_2\text{O}$  as red liquor—1·5 : 1·0.

#### NO. 1 EXPERIMENT.—NOVEMBER, 1881.

	Vat Liquor.	Red Liquor.	Salts.
$\text{Na}_2\text{S}$ .....	= 1·36 .....	3·121 .....	mil.
$\text{Na}_2\text{S}_2\text{O}_3$ .....	= 1·96 .....	5·350 .....	3·11
$\text{Na}_2\text{SO}_4$ .....	= 6·00 .....	19·02 .....	2·318

Calculated as before :—

$\text{Na}_2\text{SO}_4$ mechanically carried over	= 1·11%
due to $\text{Na}_2\text{S}_2\text{O}_3$ acid	= 1·88

Total increase	= 2·99.
Loss of $\text{Na}_2\text{O}$ =	412.

#### NO. 2 EXPERIMENT.—JANUARY, 1885.

	Vat Liquor.	Red Liquor.	Salts.
$\text{Na}_2\text{S}$ .....	= 5·75 .....	1·268 .....	0·117
$\text{Na}_2\text{S}_2\text{O}_3$ .....	= 1·718 .....	6·91 .....	2·111
$\text{Na}_2\text{SO}_4$ .....	= 6·816 .....	23·150 .....	

This experiment gives :—

$\text{Na}_2\text{SO}_4$ mechanically carried over	= 1·492
due to increase in $\text{Na}_2\text{S}_2\text{O}_3$	= 2·10

Total increase	= 3·592
----------------	---------

Loss of $\text{Na}_2\text{O}$ =	521.
---------------------------------	------

#### B. WORKS.—FURNACING OF SALTS.

Coal to 100  $\text{Na}_2\text{O}$  as Carb. ash = 0·9560 : 1.

	Salts.	Finished Carbonated
$\text{Na}_2\text{S}$ .....	mil.	mil.
$\text{Na}_2\text{S}_2\text{O}_3$ .....	341 .....	282
$\text{Na}_2\text{SO}_4$ .....	2·3185 .....	2·779
2·775 - 2·3185 =	456	increase of sulphate.
Loss of $\text{Na}_2\text{O}$ =	2%	

#### B. WORKS.—RED LIQUOR TO CAUSTIC ASH.

Ratio coal to 100  $\text{Na}_2\text{O}$  as caustic ash = 2·18 : 1·0.

$\text{Na}_2\text{S}$ .....	3·121 .....	0·173
$\text{Na}_2\text{S}_2\text{O}_3$ .....	5·350 .....	6·740
$\text{Na}_2\text{SO}_4$ .....	19·020 .....	20·382

Increase of sulphate	= 1·362%
----------------------	----------

Loss of $\text{Na}_2\text{O}$	= 0·6%
-------------------------------	--------

Taking the mean of the two pan experiments, and proportioning the increase of sulphates in the two ashes, we find the total amount of sulphate capable of being introduced—from beginning to end of the operations—to be thus distributed on 100 of  $\text{Na}_2\text{O}$  :—

$\text{Na}_2\text{SO}_4$ mechanically carried over	= 1·301%	$\text{Na}_2\text{O}$ lost.
due to hyposulphites	= 2·140	= 1·68%
introduced in furnacing	= 72	= 1·36
Total introduced	= 4·261%	= 3·28%

It will now be noticed that these figures place the amount of total sulphate introduced about five times higher than the estimate of Moorhouse, and approximate more closely to that of Weldon. Of course it will be readily apparent that differences of conditions and environment may account to a large extent for the divergence. As regards the proportion of the total sulphur in the fuel employed absorbed by the alkali in course of manufacture, the ratios which I have established in the various stages as subsisting between fuel and  $\text{Na}_2\text{O}$  dealt with, afford the necessary data. In A Works, the proportion of sulphur absorbed from beginning to end of the operations is 7·42%.

In B Works the percentage is 10·1%.

Analysis of the revolver gases for sulphurous acid before entering and after leaving the salting-down pan place the proportion rather higher.

To sum up, my figures, when averaged, would point to the following conclusions, which I have drawn up in a tabulated form on 100  $\text{Na}_2\text{O}$  :—

	Alkali lost.	Sulphate introduced.
Salting-down pan .....	43% .....	3·22%
Carbonated ash (1·5) furnaces .....	116 .....	2·67
Caustic ash (1·0) furnaces .....	192 .....	41
	758%	3·927%

Finally, it might be of interest to the members if those who have worked with pans fired from underneath would state in how far the extra fuel employed in that method compensates for the above and other disadvantages of the overhead evaporation of alkaline liquors.

Next Meeting, April 23rd.—"On Insecurity of Written and Printed Documents," by Mr. J. Jameson. "Some Account of Recent Progress with the Jameson Coking Process," by Mr. J. Jameson. "On some Practical Results of the work done by Messrs. Larkin's Patent Salt Cake Furnace at the St. Bede Chemical Company's Works, East Jarrow," by Mr. W. Rendelson.

Meeting held 5th March, 1885, in the Lecture Theatre of the Durham College of Science.

MR. B. S. PROCTOR IN THE CHAIR.

ON THE PROPOSED STATUE TO NICOLAS LEBLANC: ON THE RECOVERY OF SULPHUR FROM ALKALI WASTE: ON A FURNACE FOR CHEMICAL OPERATIONS WHICH IS NEITHER AN OPEN FURNACE NOR A CLOSE FURNACE; AND ON THE MANUFACTURE OF CHLORINE FROM OXYCHLORIDE OF MAGNESIUM.

BY WALTER WELDON, F.R.S.

In the Address which I had the honour to deliver in this theatre in July last, I spoke as though a statue had been recently erected in France in memory of the author of the most beneficent chemical invention which has yet been made by man, Nicolas Leblanc. No such statue has, however, been erected; and I am here this evening mainly for the purpose of correcting, on the spot at which it was committed, the error on this point into which I then fell.

Within the preceding eighteen months, I had read, not in one journal only, but in many journals, that a certain municipality had decided to erect a statue to Leblanc. I had read in the *Comptes Rendus*, that eloquent address to the Académie des Sciences, by its then Perpetual Secretary,—not only the greatest chemist, but nearly if not quite the greatest orator of his time: Jean Baptiste Dumas, now, alas! no longer among us,—which commences: "La municipalité d'Issoudun a résolu de consacrer par un monument la mémoire d'un glorieux enfant de cette cité, le créateur de l'industrie de la soude artificielle." And I shared, not only with many of my own countrymen, but with many Frenchmen, the belief that this resolution had been carried into effect.

The statement founded upon this belief which I made here in July has been reported in the Journal of our Society. It ought therefore to be corrected therein. Except, however, abstracts of matter published elsewhere, nothing can appear in our Journal

which has not first been communicated, either to the Society at large, or to one of its Sections; and hence the main motive of the communication which I have sought permission to make to its Newcastle Section this evening.

The project of erecting at Issoudun a monument to Leblanc dates from 1856: the year of the publication of that famous "Rapport relatif à la Découverte de la Soude Artificielle," drawn up by Dumas, on behalf of a Committee of the Academy of Sciences consisting of Dumas, Thenard, Chevreul, Pelouze, Regnard, and Balard: which establishes so conclusively that Leblanc really was the author, and the sole author, of the process which bears his name, and that the attempt of one of his old partners, Dizé, to claim the credit of that great invention was dishonest and unfounded. It was then believed that Issoudun was Leblanc's birthplace; and the leading Literary Society of the ancient province of Berry, of one division of which Issoudun is the capital, initiated the idea of erecting there a monument to the man most useful to his fellows that that province could claim to have produced. Only local subscriptions were sought; few were obtained; and the project had to be abandoned. It was revived in 1877, and again in 1881; in each case with the same result as in 1856. At length, in 1883, it was adopted by the "Consultative Chamber of Arts and Manufactures" of Issoudun, with the concurrence of the Municipal Chamber of that city; and for some months there seemed every prospect that this time it would certainly be realised. Only for some months, however; for in November, 1883, the first-mentioned of these two Chambers came to a decision with respect to it which shows that at Issoudun local patriotism is confined within most curiously narrow bounds.

One of the most remarkable figures in the intellectual society of Paris of to-day, is that of a distinguished painter, who for the last fourteen years has been afflicted with blindness—M. Auguste Anastasi. Humble in his estimation of the talent which enabled him to produce, before his great affliction fell upon him, works so esteemed by others that they have provided adequately for his later years, this chivalrous blind artist is proud indeed of one thing—namely, that he is a grandson of Nicolas Leblanc. In 1883, soon after the Chamber of Arts and Manufactures of Issoudun had decided to accomplish the erection in that town of a monument in memory of his illustrious ancestor, there came into the possession of this gentleman some family papers, which led him to doubt the accuracy of the belief which at that time obtained with respect to the date of his grandfather's birth; and the researches which he at once set on foot with a view to clearing up this point resulted in the discovery, not only that Leblanc was born in 1742, and not in 1753, as had been believed for nearly three-quarters of a century, but also that he was born, not at Issoudun, but at a village near Issoudun—namely, Ivoy-le-Pré. M. Anastasi at once communicated this last-mentioned discovery to the Chamber of Arts and Manufactures of Issoudun; and the members of that body regarded it as showing that a statue to Leblanc in their unquestionably ancient but apparently not very enlightened little town "had no longer any *raison d'être*." Upon the principle of which conclusion, that statue of George Stephenson which one sees from the door of this building would have been in place at Wylam, but is out of place in the capital city of the district in which Wylam is situated.

The work which was thus abandoned by the Issoudunites is now, however, in course of accomplishment; and our own country, which is certainly the one which has profited most by the invention of the art

of obtaining soda from salt, has an opportunity of taking part in it. It is now in the hands of a committee in which France is represented by nearly all her leading chemists, including Berthelot, Bous-singault, Becquerel, Cahours, Debray, Frémy, Friedel, Péligot, and Schloëssing, by eminent men who are not specially chemists, including Pasteur, De Freycinet, and the Count de Lesseps, and by all her largest chemical manufacturers; and in which Germany is represented by Professor Hofmann of Berlin, Belgium by M. Solvay, and this country by three Vice-Presidents of our Society, Sir Henry Roscoe, Colonel Gamble, and myself. France has already subscribed liberally; thanks to M. Solvay, Belgium holds a prominent place on the subscription list; under the auspices of Professor Hofmann and Mr. Hasenclever, influential committees are being formed for the collection of subscriptions in Germany and Austria; and the three English members of the central committee have undertaken to bring the matter under the notice of every soda maker in Great Britain. The present is certainly not a propitious moment at which to ask British Leblanc soda makers to write cheques; and I am not concerned to try to maintain that to erect monuments to departed benefactors is our highest duty. But it happens to be just now that the opportunity presents itself of doing for Leblanc what was long ago done in this country for James Watt.—I put it in that way, because I think that Dumas was certainly right in regarding the Leblanc soda process as the invention of the last century next in practical importance to the steam engine; it would at least be unbecoming that we, who manufacture twice as much Leblanc soda as all the rest of the world put together, should be surpassed by any other nation in our willingness to contribute to the acknowledgment now in question of the indebtedness of all mankind to an invention which exceeds in practical importance all others of modern times, one only excepted; and other countries are doing their part in the matter so well, that the total sum which one need wish to raise in this country in respect of it is so small,—say some £600 or £700 or so,—that if only every English soda maker would contribute something, the amount required from each would be quite inconsiderable.

Before passing to other matters, I would ask permission to mention that M. Anastasi has recently written a biography of Leblanc,\* which was published at Paris last summer, and which I believe that Messrs. Hachette & Co., of 18, King William Street, Strand, London, would send by post to any one in Great Britain in exchange for two shillings. Though its details are necessarily scanty, it tells the story of Leblanc's career much more fully than that story had been told before; and a more deeply pathetic history of a human life is scarcely, I think, to be found in all literature. Of the new facts stated in it, I will leave to be gained from the book itself all but just one: from which it appears that in travelling to Paris by Calais or Boulogne one probably traverses, and if one does not actually traverse, passes within a stone's throw of, the spot where black-ash was first manufactured, and the spot on which Leblanc died by his own hand. It is usually stated that his death took place in a hospital for the poor, but it really took place in his own house; that house was within the walls of his works; and upon a portion of the site of his works now stands the railway station of St. Denis.

Having thus corrected the inaccurate statement

\* "Nicolas Leblanc; sa Vie, ses Travaux, et l'Histoire de la Soude Artificielle." Par. Aug. Anastasi, ancien artiste peintre, Chevalier de la Légion d'Honneur, petit-fils de Nicolas Leblanc. Paris: Hachette.

made by myself in this theatre last July, I will ask permission to proceed to refer to certain comments on the process proposed by Dr. von Miller and Herr Opl for the recovery of sulphur from alkali waste, which occur in the very interesting paper by Professor Divers which was read before this Section at its meeting in November. Of the value and importance of Dr. Divers's work on the chemical history of calcium sulphides and hydrosulphides, it would be difficult to speak too highly; but he has been misled—evidently in large measure by imperfect information with respect to Von Miller and Opl's methods of procedure—into basing on some of the results of that work quite erroneous conclusions with respect to a process, one part of which might, I think, be turned to account in this district.

After having pointed out two very real objections to an earlier proposal, by Herr Opl only, for causing the calcium sulphide of alkali waste to enter into solution as calcium sulphhydrate, and having added that "a third objection is that calcium sulphide is too slow for technical purposes in combining with hydrogen sulphide, according to our experiments on the small scale," and that "a fourth difficulty is that the calcium hydroxide, and some, at least, of the carbonate always present in alkali waste, have also to be saturated with hydrogen sulphide," Dr. Divers goes on to say: "Opl's later process, or, rather, Opl and Von Miller's process, is equally unpromising. A solution of calcium hydrosulphide having been prepared from alkali waste, this is to be made, by boiling, to give up its hydrogen sulphide. Part of this is to be converted into sulphur or sulphuric acid at pleasure, and the rest is to be used in preparing a fresh solution of calcium hydrosulphide by dissolving out with it in water the sulphide of alkali waste. Not only are there the objections which apply to the other process, that hydrogen sulphide by no means quickly and readily dissolves calcium sulphide, and that it has to saturate the free lime in the waste, but there are obviously others. A solution of calcium hydrosulphide only slowly decomposes, even when vigorously boiled, unless the atmosphere over it is rapidly changed and the liberated hydrogen sulphide in this way carried off; and, therefore, the expulsion of the last portions of hydrogen sulphide will involve the generation of much steam, and this steam has to be condensed and the gas cooled before it comes to the moist waste. Another difficulty to be met, is to force this gas into the closed vessel holding the waste, since without pressure it could never be passed with any speed into the waste and yet be all absorbed."

Now, to deal first with those of these supposed objections to the process of Messrs. von Miller and Opl which relate to that portion of it which consists in treating waste by  $H_2S$ , in order to bring the calcium sulphide of the waste into solution as calcium sulphhydrate, this part of that process has been in industrial operation for now nearly two years, and experience has shown that it is open to Dr. Divers's criticism of it only on one point. The operation is not performed in "a closed vessel;" it involves no "forcing," or pumping, of sulphuretted hydrogen, either "under pressure" or otherwise; the sulphuretted hydrogen is absorbed as rapidly as it can be practically supplied; and although that sulphuretted hydrogen does react on any calcium hydrate contained in the waste treated by it, if it attacks at all the calcium carbonate of the waste, the extent to which it does so is quite inappreciable.

With pyrites at threepence per unit, it is obvious that a process directed solely to the recovery of sulphur from alkali waste, and yielding that sulphur only as sulphuretted hydrogen, can have little chance of adoption; and hence, at least until there shall

have been realised some very cheap method of treating  $H_2S$  for the separation of its sulphur in the free state, those of the proposals of Dr. von Miller and Mr. Opl which are criticised by Dr. Divers in the passages which I have quoted, taken by themselves, would have little or no practical interest. It is only because one of those proposals has been proved applicable with advantage as part of a process, having a certain interest for this district, of which the recovery of sulphur from alkali waste is simply a secondary result, that I take this opportunity of submitting to you certain facts relating to it with which Dr. Divers, when he wrote his paper read here in November, was obviously unacquainted.

While it was at the Alkali Works of Hrischau, in Moravia, of which Dr. von Miller is one of the proprietors, Mr. Opl being chemist there, that the treatment by  $H_2S$  of a mixture of waste and water, so as to dissolve out the calcium sulphide of the waste as calcium sulphhydrate, was first put into execution; as soon as this method of getting the sulphur of waste into solution was found to be a really practicable one, it was put aside at Hrischau, pending the result of that work in respect of methods for the obtaining of the sulphur of calcium sulphhydrate as free sulphur which Dr. von Miller and Mr. Opl are still earnestly pursuing. Almost simultaneously, however, with its proposal by these chemists, simply as a step towards the recovery of sulphur, it was proposed also, by M. Lombard, of Marseilles, as part of a process for the manufacture of "dicalcic phosphate;" and that nearly two years' experience of it to which I have referred has taken place, not at Hrischau, but, in connection with this process of M. Lombard's, at Rassuen, in the south of France.

The old method of manufacturing "dicalcic phosphate" consists in dissolving a suitable phosphatic material in aqueous hydrochloric acid, and then precipitating the phosphoric acid of the resulting solution by means of finely divided calcium carbonate. The phosphate obtained in this way, however, is never pure, by reason of some of the calcium carbonate always getting so coated with insoluble phosphate that contact between it and the solution in which it is present cannot take place. Seeking to become able to obtain a richer precipitated phosphate than had as yet been obtained industrially, and seeing that he could hope to do this only by means of a precipitant which could be employed in the state of solution, M. Lombard was at length led to the idea of employing as the required precipitant solution of calcium sulphhydrate, obtained by dissolving the calcium sulphide of alkali waste in aqueous solution of sulphuretted hydrogen. The process in which he does this was got to work at Rassuen, on a small but industrial scale, early in 1883; it has been in operation there ever since; and a much larger than the original plant for it is now being constructed there.

Of the sulphuretted hydrogen which is liberated in the first operation of M. Lombard's process, by the reaction upon each other of solution of phosphoric acid and solution of calcium sulphhydrate, half of course corresponds to the sulphuretted hydrogen which was used as such in the preparation of that solution of calcium sulphhydrate, and must be employed for the preparation of another quantity of solution of that body, only the remaining half of it being available for the separation of free sulphur from it, or for use, as at Rassuen, as a source of  $SO_2$ . The  $H_2S$ , however, is not, as Dr. Divers supposed when he wrote the paper read here in November, divided initially into two portions: one to be sent directly to burners, and only the other into the apparatus in which it is to react on waste; but the

whole of the sulphuretted hydrogen is sent, not into a "closed vessel," containing merely "moist waste," but into the first of a series of three vessels, charged with a mixture of waste with more than its weight of water: the first of which three vessels communicates with the second, the second communicating with the third, the third communicating with apparatus for the combustion of  $H_2S$  into  $SO_2$  and vapour of water, and this last communicating with vitriol chambers. Each of the three absorption vessels is furnished interiorly with a mechanical agitator, which is kept in motion throughout the operation performed in them. The whole of the sulphuretted hydrogen enters, as I have said, the first of the three vessels; a portion of it is absorbed in that vessel; and the remainder of it passes on into the second vessel. Of the  $H_2S$  which thus enters the second vessel, a portion is absorbed therein, the remaining portion passing on into the third vessel; and from the third vessel that portion of the sulphuretted hydrogen entering it which is not absorbed in it passes on to the combustion apparatus. The  $H_2S$  has not to be forced into the absorption vessels, but is drawn into them: partly by the draught occasioned by the absorption of some of it in those vessels, and partly by draught from the combustion apparatus and the vitriol chambers. The necessary division of the total quantity of  $H_2S$  into the proportion of it which may be burned, being the proportion of it, per operation, which represents the quantity of sulphur recovered from waste in that operation, and the proportion of it which may not be burned, and which may be regarded as one and the same quantity of  $H_2S$ , kept constantly in circulation, and used continually over and over again for dissolving calcium sulphide out of successive quantities of waste, is effected in the easiest possible way, simply by duly adjusting to each other the total quantity of  $H_2S$  evolved in each operation and the quantity of waste charged into the absorption vessels.

In M. Lombard's process,—and it is only in connection with some such process as his that there can be as yet any question of the preparation of calcium sulphhydrate from alkali waste,—the only influence of the presence of calcium hydrate in the waste treated is to diminish the quantity of sulphur recovered from waste, in the state of sulphuretted hydrogen, obtained as a secondary product of the process, per given quantity of the phosphate which is its primary product. When there is no calcium hydrate in the waste employed, one ton of sulphur from waste is obtained, as sulphuretted hydrogen, per somewhere about three tons of dialcic phosphate; and seeing that, at the present price of pyrites, a ton of pure sulphuretted hydrogen, for use merely as raw material of the manufacture of sulphuric acid, cannot be regarded as worth more than thirty shillings, for the quantity of secondary product, per that quantity of primary product, to be reduced, by the presence of calcium hydrate in the waste employed, to say eighteen hundredweight, is simply to make the cost of the primary product greater in the latter case than in the former by about one shilling per ton. As regards the calcium carbonate of the waste employed, it has practically no prejudicial influence whatever, sulphuretted hydrogen not attacking this constituent of waste until practically all its calcium sulphide and calcium hydrate have been dissolved out, beyond which point the operation is not carried; and though Dr. Divers supposes, I believe erroneously, that sulphuretted hydrogen generated from solution of calcium sulphhydrate by Dr. von Miller's method, "must be cooled before" it can be used for the preparation of a further portion of sulphhydrate, in M. Lombard's process, at any rate, the  $H_2S$  does not require cooling,

being evolved at a temperature little, if at all, above that of the atmosphere. Lastly, the operation of bringing into solution as calcium sulphhydrate the calcium sulphide of alkali waste, by the method which I have described, is not a costly operation; requiring fuel only for raising the small quantity of steam required to keep in motion the agitators in the absorption vessels, and labour only for raising that steam, charging those vessels, and discharging them.

We may, therefore, I think, take it that calcium sulphhydrate is now readily and cheaply obtainable for use in any process, to be performed in or in the neighbourhood of Leblanc soda works, in which that body can be employed as a re-agent: provided only that the process be one—such, for example, as M. Lombard's—in which the sulphur of the calcium sulphhydrate, or, if not the whole of that sulphur, at least half of it, is evolved as  $H_2S$ . For what cannot, I think, fail to become a very important industry in this district—namely, the manufacture of phosphates of lime from the phosphoric acid of the slag of the basic steel process, the question of using as the necessary precipitating agent solution of calcium sulphhydrate prepared by the method of Messrs. von Miller, Opl, and Lombard, and so obtaining a richer phosphatic product that can be obtained by means of any other precipitant industrially available, and at the same time recovering the sulphur of an equivalent or nearly equivalent quantity of the calcium sulphide of alkali waste—certainly seems worthy of at least being studied.

As Dr. von Miller's method of decomposing the solution of calcium sulphhydrate obtained by his, Opl, and Lombard's method can have very little practical interest until means shall have been realised of cheaply obtaining free sulphur from sulphuretted hydrogen, I will ask permission to devote to it only the very few sentences necessary to indicate its real nature—for the idea of it which is conveyed by Dr. Divers's paper is not an entirely accurate one—and its present position. Dr. Divers's statement that "solution of calcium hydrosulphide decomposes only slowly, even when vigorously boiled, unless the atmosphere over it is rapidly changed, and the liberated hydrogen sulphide in this way carried off," is of course absolutely accurate; but it has scarcely any relevance to Dr. von Miller's method of procedure, which consists, not in merely "boiling" the solution in question, but in evaporating it nearly to dryness. This method of procedure no doubt involves "the generation of much steam," and "this steam," as Dr. Divers says, "must be condensed;" but the condensation of steam is not a difficult operation, and the only practical question relating to that steam is, what is the cost of raising it? On this point Dr. von Miller informs me that such experience as he has yet had with respect to it leads him to conclude that the evaporation of the quantity of solution of calcium sulphhydrate, the evaporation of which yields the quantity of sulphuretted hydrogen containing two tons of sulphur, being the quantity of such solution which in his process has to be evaporated per one ton of sulphur recovered from alkali waste, can be effected by 18 ton of slack, and that in his district, at any rate, the value, merely for use in agriculture, of the 2 tons 6 cwt. of chemically pure but very dense crystallised calcium hydrate which are obtained as a secondary product of the evaporation of the quantity of solution of calcium sulphhydrate in question, is fully equal to the cost of performing that evaporation, for fuel and labour combined. The one difficulty which he has really had to encounter in his endeavour to realise on the large scale the decomposition of calcium sulphhydrate by the mere evaporation of its aqueous solu-

tion is that of providing suitable vessels in which to perform that evaporation: vessels, the materials of which shall be attackable neither by calcium sulphhydrate nor by hydrogen sulphide. He believes that he has recently come to see a satisfactory way out of this difficulty; but at this season building operations are impracticable at Hirschau, and it will not be till towards the close of next autumn that the practicability or otherwise of his latest ideas on this subject will have been adequately tested.

Dr. von Miller is perfectly conscious that even when he shall have succeeded in obtaining command of suitable apparatus in which to effect the decomposition of calcium sulphhydrate by his method, that method can have little practical value until it shall have been supplemented by a cheap means of decomposing sulphuretted hydrogen in such manner as to obtain its sulphur in the free state. Though hydrogen sulphide is by no means a very stable body, none of the many proposed such methods of decomposing it have yet succeeded on the large scale; even the Claus process, which at one time seemed very hopeful, having as yet given only incomplete results. Dr. von Miller is at present working on an idea for the accomplishment of the object in question, which, whether or not it be destined to prove more fortunate than its many predecessors, is at least interesting as constituting quite a new departure in its line: that idea being to burn the hydrogen only of sulphuretted hydrogen, not by gaseous oxygen, but by the solid oxygen of calcium sulphate.

Dr. von Miller has found that if sulphuretted hydrogen be passed over heated calcium sulphate, the calcium sulphate becomes reduced to sulphide, and there passes off a mixture of vapour of water and vapour of free sulphur. He has also found that if a current of air be then admitted to the residual calcium sulphide, the latter combines with some of the oxygen of the air thus admitted to it, with considerable evolution of heat, the original quantity of calcium sulphate being thus reconstituted for use again. The oxygen which combines with the hydrogen of the sulphuretted hydrogen treated by this process is thus atmospheric oxygen, but atmospheric oxygen no longer having nitrogen associated with it; so that if any of the sulphuretted hydrogen escapes decomposition in the first instance, or if any of its sulphur is oxidised into  $\text{SO}_2$ , the  $\text{H}_2\text{S}$  or  $\text{SO}_2$ , which in such case passes from the apparatus in which the process is performed, instead of being mixed, as under corresponding circumstances in the Claus process, for example, with so much inert gas as to preclude its utilisation, is mixed only with vapour of sulphur and vapour of water, and when these have been condensed out it remains perfectly pure. At Oldbury, Messrs. Chance Brothers have made some small experiments on this process; and they have found that, in the laboratory at any rate, it is easy of execution, and that none of the sulphur of the sulphuretted hydrogen treated by it undergoes oxidation, provided only that the sulphuretted hydrogen be always sent into the apparatus containing the heated calcium sulphate at such speed that a slight proportion of it shall pass out undecomposed.

Other new processes for the recovery of sulphur from the residual product of the Leblanc soda process are now under experiment, but time will not permit me to touch upon them; and I will now proceed, with your permission, to briefly indicate the nature of the furnace invented at Salindres for use in the process of manufacturing chlorine from oxychloride of magnesium.

That method of manufacturing chlorine was first made public by the address, delivered in this theatre, to which I have already referred. Shortly after-

wards, one of your members, who bears a name which must always hold a foremost place in the history of metallurgical invention, Mr. Hugh Lee Pattinson, junior, wrote to that great daily newspaper which is one of the many things for which this city is renowned far and wide, for the purpose of pointing out certain supposed objections to that process, in order, as he put it, "that an undue amount of importance" might "not be attached to" the address in which that process and certain probable consequences of it were touched upon, "by those unable, of their own knowledge, to supply a criticism" of it. For the comfort of such persons, Mr. Pattinson "supplied a criticism," one of the points of which was that the fundamental reaction of the chlorine process in question must be performed, either in an open furnace, in which case the chlorine yielded by it would be mixed with products of combustion, or "in a retort or close furnace," costly alike for fuel and for wear and tear. I replied that the apparatus in which that reaction is performed at Salindres is of the nature neither of an open furnace nor of a "close" one; and I have been surprised to find that there are those who have been unable to understand how this could be.

Our French friends have a proverb which declares that "a door must be either open or shut;" but it is not the case that a furnace must be either an "open" furnace or what we call a "close" one: meaning by an "open furnace," one the charge in which is heated by direct contact with the products of the combustion of the fuel employed, and by a "close furnace" one in which the charge is heated, without coming into contact with products of combustion, by heat applied to the exterior of the furnace, and transmitted to the charge contained therein through the material of which the furnace is constructed. There is of course another kind of furnace than either of these. A furnace which was in use before the dawn of history, the principle of which was known to and applied by pre-historic man, a furnace which exists to-day in greater numbers than any other, and which has rendered and is still rendering more important service to humanity than all other kinds of furnaces put together, is neither an "open furnace" nor a "close" one. Need I say that I refer to the baker's oven?

To prepare the staff of life, one has to roast small masses of a slightly fermented intimate mixture of flour and water. When he has charged these into his furnace, or "oven," the baker does not pour in upon them flame and heated products of combustion; and hence his furnace is not an open furnace. Nor does he apply heat to the exterior of his oven, and so roast his loaves by heat transmitted to them through the substance of its floor, walls, or roof; and hence his oven is not of the nature of a "retort or close furnace." What he does is to heat up his oven before his loaves are put into it, and the loaves are then roasted, or "baked," by means of heat which was applied to and stored up in the bricks of which the oven is constructed before the loaves entered it. The new chlorine furnace in question is upon precisely the same principle; and M. Pecliney and I, in speaking of it together, always call it the "four de boulanger."

It consists of a series of vertical chambers, the thickness of the dividing walls of which is considerably greater than the width of the spaces between them. Before charging these chambers with oxychloride of magnesium, products of combustion are passed through them, until their dividing walls are raised to a certain temperature. The products of combustion which have traversed the series of chambers go first through a regenerator and then to appa-

ratus in which most of the heat still retained by them is utilised for the evaporation of the solution of magnesium chloride with which the process commences. When the dividing walls of the furnace have been heated sufficiently, the admission of products of combustion is arrested, and the chambers are charged, through doors at the top of each of them, with magnesium oxychloride in small lumps. By absorption of some of the heat previously stored up in the massive dividing walls of the furnace, these lumps of oxychloride rapidly become raised to such temperature that the oxygen of the air which is now admitted into the furnace can react upon them, with the result that their chlorine becomes replaced by some of that oxygen, and that there passes off a mixture of free chlorine, nitrogen, excess of air, and vapour of hydrochloric acid: which mixture passes first to apparatus in which its vapour of HCl is condensed out from it, its gases then passing on into mechanical bleaching powder chambers. When this replacement of the chlorine of the magnesium oxychloride by atmospheric oxygen has become complete or nearly so, the residual magnesia is discharged by doors at the bottom of each compartment of the furnace, and the furnace is then ready to be heated up again, for another operation.

The furnace invented at Salindres for the oxychloride of magnesium chlorine process thus avoids equally both the alternative difficulties, one or other of which Mr. Pattinson declared that the process "must" necessarily encounter. The chlorine liberated in that furnace is not mixed with products of combustion, nor is the material treated in it heated by the costly method of transmitting to it, through the substance of the vessel containing it, heat applied to that vessel externally. To which allow me to add that the furnace is not costly of construction; that it is subject only to a moderate amount of wear and tear; that it is obviously economical of fuel; and that there seems every likelihood that the manufacture of chlorine from chloride of magnesium is by no means the only purpose to which it will prove capable of being applied with advantage.

To the chlorine process for which this furnace was invented, Mr. Pattinson further objected that the chlorine yielded by it is hot chlorine, requiring to be cooled before it can be applied to the manufacture of bleaching-powder: as though black ash did not require cooling before it can be lixiviated; as though it were an objection, alike to the Leblanc soda process and to the ammonia soda process, that the finished product of each respectively must be cooled before it can be packed into casks; as though it were a grave fault on the part of our method of manufacturing sulphuric acid that the gases from the pyrites burners must be cooled before they can enter the vitriol chambers; and as though it could matter in the least whether the chlorine had to be cooled or not, provided only that it be finally yielded, as chlorine which has been absorbed by calcium hydrate and has so become a constituent of bleaching-powder, more cheaply than chlorine manufactured in any other way. I may nevertheless point out that the operation by which the chlorine is cooled is not performed for the express purpose of cooling the chlorine, as Mr. Pattinson's "criticism" would imply that it is, but would equally have to be performed even if the chlorine were not hot at the stage at which that operation comes in: the case being one of a process yielding two distinct products, which two products, at an intermediate stage of the process, are mixed together, but neither of which is of any value until it is separated from the other, so that the process by which both are manufactured is not completed until the operation by which their separation

is effected has been performed, and that to say of that process that the operation by which its two products are separated is an essential part of it is to criticise it only in the sense, if any, in which it would be a criticism of the Leblanc soda process to say that its intermediate product, black ash, has to be separated into sodium carbonate and calcium sulphide, or in which it would be a criticism of the ammonia soda process to say that it is necessary in that process to split up the hydrogen-sodium carbonate immediately produced in it into normal sodium-carbonate, vapour of water, and free carbonic anhydride.

The two products are of course free chlorine and vapour of hydrochloric acid. Whereas, per 100 parts of the chlorine contained in hydrochloric acid treated by the old Weldon process, 30 parts are yielded as free chlorine and 70 parts as the chlorine of calcium chloride, per 100 parts of the chlorine of hydrochloric acid treated by the oxychloride of magnesium process, 50 parts are obtained as free chlorine, and the other 50 parts as HCl: the aqueous acid obtained by the condensation of which HCl may either be neutralised by magnesia and made to yield another 50 parts of free chlorine, or be applied to any other purpose which may be preferred. To whatever purpose, however, that HCl be afterwards applied, it must be separated from the free chlorine which is liberated concurrently with it, and the operation by which it is so separated yields the chlorine cool: no operation for the special purpose of cooling the chlorine being thus required.

Even, however, if the chlorine had to be cooled by an operation having no other object, what would that operation amount to? Supposing the mixture of chlorine and other gases to be not much more than half as rich in chlorine as it often has been, the volume, at the temperature of the atmosphere, of the quantity of it corresponding to a ton of bleaching-powder would be about 28,000 cubic feet, or scarcely more than one-sixth of the volume of the quantity of gases which has to be cooled, in the manufacture of sulphuric acid, supposing the gases from the burners to contain 7 per cent. by volume  $\text{SO}_2$ , from the temperature of the combustion of pyrites to that at which they enter the vitriol chambers, per ton of pyrites burnt. A single firm in this district, the Newcastle Chemical Works Company, burning 30,000 tons of pyrites per annum, cools per annum, from and to the temperatures I have mentioned—without Mr. Alfred Allhusen, I venture to say, considering that he is doing anything specially wonderful in so cooling a quantity of gases so enormous—about five thousand millions of cubic feet of burner gases: being a quantity little, if at all, inferior to the total quantity of gases which would have to be cooled in connection with the oxychloride of magnesium chlorine process, if there were manufactured by that process absolutely the whole of the chlorine at present produced by all the chlorine manufacturers in the world put together.

In conclusion, just four sentences, if you please, with respect to the dilution of chlorine by other gases, and the manufacture of bleaching-powder in mechanical chambers. One point of Mr. Pattinson's "criticism" was that the chlorine yielded by the process of which I have been speaking, and that yielded by a certain other process, being dilute, cannot be used in ordinary bleaching-powder chambers. So might it have been objected in the early part of this century to the proposal to use coal gas as an illuminating agent, that it could not be burned in the ancient candle-sticks. The candle-sticks have gone; and I express a most deliberate and carefully-weighed opinion in saying that the primitive bleach-

ing-powder chambers would have to follow them, even if there were no question of any change in the methods by which chlorine is manufactured. Mr. Pattinson said in the *Chronicle* that "it is always desirable, if not essential, to make it" (bleaching-powder) "with concentrated pure gas;" but that ancient superstition is not only not supported by experience of the use of dilute chlorine in mechanical bleaching-powder chambers, but all such experience goes to show that, even when manufacturing chlorine by methods yielding "concentrated pure gas," the wise course would be to deliberately mix air with that gas, in order to become able to absorb it by a method much more rational than the primitive method at present used exclusively everywhere, I believe, except at Salindres: by a method, that is to say, which not only avoids all loss of chlorine, and all nuisance arising from such loss, and is very much more rapid than the ordinary method, but which also yields much more stable bleaching-powder, and bleaching-powder much more uniform in quality, than can be manufactured by the old method, but which new method absolutely requires that the chlorine treated by it should be mixed with an inert gas, which may constantly carry off the heat liberated by the combination of the chlorine with calcium hydrate. Experience of that mechanical bleaching-powder chamber which Mr. Pattinson said that it had been "necessary to invent" for the absorption of the dilute chlorine yielded by the new processes in question, but which was really invented and used long before any experiments on those processes had been commenced at Salindres—for the absorption of the chlorine remaining in the atmosphere of ordinary bleaching-powder chambers, fed by strong chlorine from the old Weldon process, at the moment of taking down their doors, has proved conclusively that to say of a method of manufacturing chlorine that the chlorine yielded by it is diluted by other gases, provided only that those gases are inert gases, not capable of being absorbed by calcium hydrate, and that the degree of dilution is not too great, is to say that the chlorine manufactured by that process is better adapted, and not less well adapted, to the manufacture of good bleaching-powder, than if it were not diluted by other gases; and that to object to such a process that the chlorine yielded by it cannot be used in the old bleaching-powder chambers, is as though one should maintain that the modern railway system is inferior in advantage to the stage-coach system of our fathers, on the ground that railway locomotives cannot be run on ordinary roads.

#### DISCUSSION.

The CHAIRMAN: The formal discussion of Mr. Weldon's paper will take place, of course, at our next meeting; but as Mr. Weldon may not be able to attend our next meeting, perhaps those of the members present who would like to put any questions to him on the subject of his paper will do so now, while he is here to answer them.

Mr. JOHN PATTINSON: It would be interesting to know on what scale bleaching-powder is now being made at Salindres by the oxychloride of magnesium process. I presume that the magnesium chloride is obtained by decomposing by magnesia the ammonium chloride of the ammonia soda process?

Mr. STUART: Can Mr. Weldon give us any idea of the form and principle of the mechanical bleaching-powder chamber of which he has spoken? The Chief Inspector under the Alkali Acts has been pressing manufacturers to adopt some method of dealing with the residual chlorine remaining in the present chambers when the charge in them is ready to be packed,

and his proposals on this point have not met with very general approval. Perhaps Mr. Pechiney's mechanical chamber might be a solution of the difficulty. I should also like to ask which process of manufacturing chlorine at present offers the greatest promise of future success—the oxychloride of magnesium process, or the chloride of manganese process?

Mr. MORRISON: What length of time is required for the operation of manufacturing bleaching-powder in mechanical chambers?

Mr. NIXON: What are the practical difficulties of decomposing oxychloride of magnesium by atmospheric oxygen? Is the whole of the oxygen of the air used absorbed? And is the bleaching-powder made from the dilute chlorine got up to full English strength?

Mr. WELDON: Up to the present time, the successive installations at Salindres for the oxychloride of magnesium process have been upon a semi-industrial scale; but a large industrial plant for it is now in course of construction there. The magnesium chloride hitherto used at Salindres as the raw material of the process in question has been that obtained in the salt gardens of MM. Pechiney et Cie., at Giraud, in Camargue, as the mother-liquor from the manufacture of salt, by natural evaporation, from sea water. The mechanical bleaching-powder chamber in use at Salindres was devised for the express purpose of absorbing the chlorine contained in ordinary bleaching-powder chambers at the moment of taking down their doors. It is upon the principle of the horizontal revolving cylinder which was tried at Gerard's Bridge, St. Helens, many years ago. Mechanical bleaching-powder chambers, however, cannot give good results with strong chlorine. When the chlorine used in mechanical chambers is sufficiently diluted by inert gases to carry off the heat generated by the reaction of the chlorine on calcium hydrate, mechanical bleaching-powder chambers yield as strong bleaching powder as can be obtained in any other chambers. The time required for the operation of manufacturing bleaching-powder in mechanical chambers depends chiefly on the rate at which chlorine can be sent into the chambers, without raising the partially formed bleaching-powder to too high a temperature; and this depends chiefly on the degree of dilution of the chlorine. The one of the two processes referred to by Mr. Stuart which M. Pechiney and I believe to be the most promising, is the oxychloride of magnesium process. It presented a good many practical difficulties at first; but, thanks to M. Pechiney, and to the engineer of Salindres, M. Boulouvard (the inventor of a very successful form of the ammonia soda process), I believe they may all be regarded as having now been overcome. The whole of the oxygen of the air employed can be made to react on the magnesium oxychloride, but it is better to work so that only about half of it shall react.

## NEW AND LITTLE-KNOWN APPLICATIONS OF THE NITROMETER.

BY ALFRED H. ALLEN.

DOUBTLESS many of the members of the Society of Chemical Industry are in the habit of using the nitrometer, and if they have employed it for one particular purpose have probably been struck with its applicability to certain others which fall within the range of their requirements. Hence, I am prepared to find that most of the applications of the nitrometer which I intend to refer to this evening have already been made by individual members of the Society, and my excuse for bringing the matter forward must be the desirability of causing these applications made by individual members to come into more general use. Still, I believe I may claim that certain uses of the nitrometer to which I desire to call attention are strictly novel and original.

As long ago as 1847 (*Phil. Mag.* [3] xxx. 426), the late Walter Crum described a method of estimating the nitrates and analysing *gun cotton*, which consisted in passing up the nitrated substance, together with some water and sulphuric acid, into a graduated tube filled with mercury. The nitric oxide liberated in the reaction was subsequently absorbed by a strong solution of ferrous sulphate. The method of manipulation was greatly improved by Frankland and Armstrong in 1868 (*Journ. Chem. Soc.* xxi. 101), and recommended by them for the estimation of nitrates in water. Their use of a tube open at one end and closed at the other by a tap surmounted by a cup greatly facilitated the introduction of the nitrate and acid. This apparatus, which may be called the Frankland-Armstrong tube, would have come into more general use had the agitation of the lighter liquids with the mercury been more easy to effect, but the accuracy of the results yielded by it have been fully proved by Mr. R. Warrington (*Journ. Chem. Soc.*, xxxv. 376), who also found that the presence of chlorides did not interfere to any notable extent with the amount of gas obtained.

Mr. G. E. Davis states that the idea of applying the mercury process to the assay of *nitrous vitriol* was suggested to him by Dr. John Watts in 1872; and, in a paper read before the Faraday Club on January 22nd, 1878, Mr. Davis fully described the use of the Frankland tube for the assay of vitriol, which tube he used in connection with a mercurial trough. In February, 1878, Mr. Davis informs me that he connected Frankland's tube to a piece of combustion tube by means of india-rubber tubing, and used the two side by side in a burette-stand. This arrangement constituted the first form of the instrument we now call the nitrometer.

The name "nitrometer" is due to Dr. Lunge, who in 1878 published and illustrated a description of his instrument (*Berlin Berichte*, xi. 436; *Dingler's Polytechn. Journ.*, 228, page 417; *Chem. News*, xxxviii. 19).

To Dr. Lunge, then, belongs the credit of the first published description of the nitrometer, but the same instrument appears to have been devised independently at a somewhat later date by Mr. Campbell, then of the Hebburn Chemical Works.

Lunge's nitrometer possessed one decided improvement in the use of a three-way tap, which arrangement appears to have been adopted from Bunte's gas apparatus. When the nitrometer is employed for the estimation of nitrates, or the assay of nitrous vitriol, the three-way tap greatly facilitates the

removal of the acid liquid at the end of an experiment, without necessitating the complete emptying of the nitrometer. Later on I propose to show that the nitrometer furnished with a three-way tap has such important uses and advantages of its own, that it almost deserves to rank as a distinct piece of apparatus.

As ordinarily employed, the nitrometer-stand is so arranged that the open or reservoir-tube must be removed from its position and brought into close proximity to the graduated-tube, before the measure of gas in the latter can be read off, and it is therefore an advantage to have the stand so constructed that the closed and open tubes of the apparatus, which I propose hereafter to refer to as the "nitrometer" and "reservoir" tubes respectively, should be in close proximity.

Another inconvenience attending the use of the nitrometer is the persistent mercurial froth which remains after the completion of the reaction, and prevents the reading of the level of the mercury in the nitrometer tube from being taken without delay. When great accuracy is not required, this may be avoided by employing a tolerably wide tube; but, for ordinary purposes, it is preferable to adopt a plan suggested by me in a paper on the estimation of nitrates by the nitrometer, published in 1880 (*Analyst*, v. p. 181). In that paper, I proposed to make a mixture of sulphuric acid and water, in the same quantity and proportions as the acid and solution of nitrate are employed in the nitrometer-tube, and to pour this mixture on the top of the mercury in the reservoir-tube. It is then possible at once to bring the aqueous liquids in both tubes to the same level, and the incomplete separation of the mercury from the aqueous liquid becomes a matter of indifference. In the same paper, I proposed to make an experiment with a second nitrometer, in which a definite amount of nitre was used. By noting the volume of nitric oxide evolved in this apparatus, and comparing it with that obtained in the case of the liquid of unknown composition, it becomes unnecessary to make any correction for pressure or temperature; and the standard quantity of gas, when once obtained, can be kept in the tube without alteration for any length of time. If this course be pursued, it is desirable to keep a little strong sulphuric acid in the cup, to prevent any possibility of leakage.

Before leaving the question of the estimation of nitrates in the nitrometer, I may point out a source of error which appears not unfrequently to have been ignored. This is, that strong sulphuric acid has a notable solvent power for nitric oxide, and hence the full amount of gas cannot be obtained unless the sulphuric acid be diluted below that point at which its solvent power for nitric oxide becomes appreciable. Warrington and Thorpe both recommend that the strong sulphuric acid and aqueous liquid should bear the proportion of three measures to two, and my own experience is in favour of this condition.

In experiments on nitrous vitriol, made by Mr. T. Bayley at my request, to test the extent of the error from absorption of nitric oxide, he found that in the case of acid of a density of about 1.62 the extra gas obtained after further diluting the acid was fully 0.5 cc. This source of error becomes more serious when stronger acid is employed, and is not improbably the cause of the low results obtained when an excessive quantity of acid is used for the assay of dynamite in the nitrometer.

For the examination of *dynamite* and *gun-cotton*, Lunge places about 35 grammes of the sample in the cup of the nitrometer, and dissolves it in 5 cc. of concentrated sulphuric acid. The liquid is then allowed to enter through the tap, and is agitated with the

mercury in the usual way. Probably better results would be obtained if a few centimeters of water were added after the completion of the reaction.

Hitherto all employers of the nitrometer appear to have regarded mercury as the only liquid with which the instrument could be filled, and of course this is actually the case in the estimation of nitrates, since the mercury itself takes part in the reaction.

For many purposes, however, the mercury can be conveniently replaced by a dense aqueous liquid, saturated brine being most generally suitable, and the following are some of the applications to which I have put the nitrometer when filled with such a liquid.

The assay of *spirit of nitrous ether* and kindred preparations for the proportion of ethyl nitrite is a problem which has engaged the active attention of pharmaceutical chemists. Hitherto the processes for the purpose have not been very satisfactory, the one giving results nearest to the truth being that of Eykman, which consists in treating the sample with a solution of ferrous sulphate and dilute sulphuric acid, heating the mixture, and collecting the nitric oxide gas evolved. Though the process is theoretically perfect, there are certain sources of error in practice, and the apparatus is somewhat complicated, and requires skill in management. Mr. D. B. Dott has proposed to estimate ethyl nitrite by treating it with potassium iodide and dilute sulphuric acid, and estimating the amount of iodine set free by titration with a standard solution of sodium thiosulphate. The reaction which occurs in this process is expressed by the equation :—

In making experiments on Dott's method it occurred to me to measure the nitric oxide gas evolved, instead of titrating the iodine liberated, and as the reaction occurs completely and promptly at the ordinary temperature, the nitrometer is an apparatus well suited for the purpose. I have now had a large experience in the process, which is best performed in the following manner :—A nitrometer should be filled with strong brine, and 5cc. of the sample to be tested should then be placed in the cup of the nitrometer, and allowed to enter through the tap, taking care that no air gets in at the same time. About 5cc. measure of a strong solution of potassium iodide is next allowed to enter, and this is followed by about 5cc. of dilute sulphuric acid. Effervescence immediately ensues, and, if the tube be vigorously agitated at intervals, the reaction is complete in a few minutes, when the level of the liquid in the two limbs of the nitrometer is adjusted, and the volume of nitric oxide gas read off. There is no difficulty in confining the reaction to the liquid in the upper part of the closed limb of the nitrometer. The nitrometer method has been proved to give very good results with pure *sodium nitrite*, prepared from silver nitrite, and employed in known amount, and may be advantageously used for the assay of commercial nitrite of sodium. With some specimens of sweet spirit of nitre a considerable volume of nitric oxide is produced, and iodine liberated before adding the acid, the reaction probably depending on the presence of free acid in the sample. The results obtained in the nitrometer are remarkably constant, and the method furnishes a very easy means of assaying sweet spirit of nitre with considerable accuracy, which is further increased if a correction of 15cc. of NO be made for solubility of the gas. The process does not occupy ten minutes, including the calculation, and actually measures the nitrous compounds present in the sample, instead of leaving their proportions to be

inferred from a more or less complex reaction, such as the reduction of permanganate, etc. When strictly accurate results are not required, as is rarely the case in assaying such a preparation, the volume of gas need not be corrected for variations of pressure, temperature and tension of aqueous vapour, etc. 1cc. of NO at the ordinary conditions of pressure and temperature corresponds to '003184 grammes of ethyl nitrite,\* and hence 5cc. of samples of spirit of nitrous ether of reasonably good quality evolve from 25cc. to 40cc. of nitric oxide.†

Another useful application of the nitrometer is for the estimation of *urea* in its urine. For this purpose the tube is filled with brine as before, and 2cc. of the sample introduced through the tap. This is followed by 10cc. of the usual solution of bromine in caustic soda.† Before the bromised soda has time to sink through the brine it comes in contact with the urine, and the great bulk of the nitrogen gas is liberated. By now placing a clip on the india-rubber connecting-tube and agitating the contents of the nitrometer tube vigorously, the reaction is completed, and the volume of gas may be read off. Not unfrequently the reading is delayed by the existence of froth on the surface of the liquid in the closed tube, but this may be instantaneously got rid of by introducing a few drops of alcohol through the tap. In some respects it is preferable to bring the bromised soda and urine in contact with each other in a small bottle or flask

FIG. 1.

FIG. 2.

fitted with a perforated cork, and connected by narrow india-rubber tubing with the nose of the three-way tap of a nitrometer filled with brine or water (Fig. 2). A nitrometer is much better for this purpose than the device of a burette or graduated tube immersed in a tall jar of water, as is employed by Dr. Squibb and others.

\* I have had a special nitrometer (Fig. 1) constructed for me for the assay of nitrous ether preparations. The graduated tube holds 50cc., and the cup is narrow and cylindrical, and has marks at 5cc. and 10cc. above the tap. This arrangement renders the use of a pipette or other separate measuring arrangement unnecessary, as the cup can be filled to the 5cc. mark with the sample, and thus a definite amount taken for the analysis. In this case a three-way tap is of no advantage. Messrs. Culey and Preston, of High Street, Shetfield, are now prepared to supply these nitrometers to those desirous of employing the process mentioned in the text. With regard to the titration process of Mr. Dott, if the treatment with potassium iodide be effected in an open basin in presence of air, as is recommended by him, the amount of nitric found is liable to be very seriously in error; but if air be excluded, Dott's method gives fair approximate results, somewhat in excess of the truth. The process can be advantageously employed on the solution which has already been decomposed with potassium iodide in the nitrometer. The nitric oxide is allowed to escape into the air, and the brown liquid is washed into a basin, and at once titrated with decinormal thiosulphate.

† 100 grammes of caustic soda are dissolved in 250cc. of water and 25cc. of bromine cautiously added to the well-cooled liquid. In some respects it is preferable to dilute the 10cc. of this solution with an equal measure of water before introducing it into the nitrometer.

The last arrangement is well suited for the estimation of *carbonates*, the sample being placed in the flask, and the acid for its decomposition contained in a small tube in the usual way. This amounts to a suggestion to employ a nitrometer in place of the measuring tubes of Scheibler's carbonic acid apparatus. Of course the usual corrections for solubility of the gas in the acid liquid, etc., apply as much in one case as in the other.

The nitrometer may also be very conveniently used for the assay of commercial *peroxide of hydrogen*, for which it was first employed by Mr. G. E. Davis, who filled the nitrometer with mercury and operated on 1cc. of the sample, which he agitated with 5cc. of a saturated solution of potassium bichromate. Under these circumstances Mr. Davis found the peroxide of hydrogen to be split up into water and oxygen, the bichromate remaining unchanged, and this observation has been subsequently confirmed by Mr. W. H. Symons. It is usual to express the strength of peroxide of hydrogen in terms of volumes of oxygen obtainable therefrom, and hence the nitrometer is well suited for its assay.

According to my own experience, the reaction of bichromate of potassium on peroxide of hydrogen does not occur so promptly or completely as could be wished, and I have therefore substituted for it an acidulated solution of permanganate of potassium. I prefer to operate as follows:—

The nitrometer is filled with a saturated solution of sodium or magnesium sulphate.\* 1cc. of the sample is then introduced through the tap, and this is followed by a strong solution of potassium permanganate, which has been previously acidulated with sulphuric acid. The reaction occurs very promptly, and the permanent coloration of the contents of the tube suffices to show that an excess of the permanganate has been employed. When acidulated permanganate is used the reaction is as follows:—

Mr. Kingzett and these chemists have independently proved the truth of the equation by adding standard permanganate to hydrogen peroxide (in presence of free acid) contained in a Woulff's bottle arranged so that the evolved oxygen could be collected and measured. The accuracy of the results obtained by permanganate was checked by estimating the iodine liberated by the hydroxyl from potassium iodide. Hence, when acidulated permanganate is employed for decomposing hydroxyl, only one-half of the oxygen gas liberated comes from the samples, the other half being derived from the re-agent. Therefore, 1cc. of a sample of peroxide of hydrogen, described as of "10 volumes strength," ought to give 20cc. of oxygen in the nitrometer. If an acidulated solution of potassium bichromate be substituted for the permanganate the reaction occurs very promptly, a double volume of oxygen being evolved, but for some unexplained reason the results are sensibly lower than those obtained with permanganate.

While the nitrometer is frequently used as an instrument in which to evolve and measure gas, it has not met with such a wide application as it deserves for the purpose of *absorbing gases*. But, as a matter of fact, by the aid of two of Lunge's nitrometers, having their three-way taps joined by a short piece of india-rubber tubing, we can extemporise an apparatus for gas analysis capable of a variety of applications. This is practically done by Bunte in

his gas apparatus, but, curiously enough, in the method of working he prescribes, he makes little or no use of his cup, preferring to introduce his re-agents by a somewhat complicated manipulation through a tap at the bottom of the nitrometer. In Elliott's gas apparatus full use is made of the cup arrangement, but instead of employing a three-way tap, Elliott uses a special arrangement for transferring the gas to the measuring tube.

Having not unfrequently to make analyses of blast-furnace and Siemens gases for technical purposes, the importance of having a rapid and moderately accurate method of gas analysis has forced itself on my attention, with the result that I have devised a very simple apparatus, combining the various advantages of the instruments of Stead, Bunte and Elliott. The following is a description of the apparatus in its simplest form.

The measuring tube A (Fig. 3) ends at the top in a capillary tube bent at right angles, and furnished with a tap E. Two platinum wires are sealed into the upper part for passing an electric spark when required. The lower end of the tube is drawn out and attached by india-rubber to a T-piece, by which it is connected to the parallel open tube B and to the

FIG. 3.

reservoir D. In cases where the apparatus is to be used with mercury, the vessel D should be replaced by a reservoir sliding in vertical grooves, and adjustable by means of a pulley. The tubes A and B are enclosed in a glass cylinder, which is filled with water, the temperature of which is usually found in practice to remain constant during the whole time required for a gas analysis. The capillary tube at the top of A is connected by a few inches of narrow india-rubber tubing with the three-way tap of a nitrometer. The nitrometer-tube I prefer to employ has a globular enlargement just below the tap, and is furnished at the bottom with two taps L and M, by the latter of which it is connected with a reservoir of water N. A Lunge's nitrometer can be used as a makeshift for the special tube shown in the diagram, clips being substituted for the taps at the bottom. The apparatus can be worked equally well with either mercury or water, but to avoid repetition, I will describe the manipulation when water is used, and assume the gas to be analysed to be a mixture  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{CH}_4$ ,  $\text{C}_2\text{H}_6$ ,  $\text{O}$ ,  $\text{H}$ , and  $\text{N}$ .

Before commencing an operation the nitrometer is detached from the measuring tube, the tube E is opened and the reservoir D raised, so as to drive out the whole of the air from the measuring tube, and its capillary continuation E is then closed, the reservoir lowered, attachment made with a receptacle containing the gas to be analysed, when, on the tap E being re-opened, the gas flows into the measuring tube. E is closed and the height of the reservoir D adjusted until the water in A and B stands at the same level.

\* If brine be used there is a tendency to error from the evolution of chlorine.

The measure of the gas taken for an experiment is then read off, and the temperature of the surrounding water and height of the barometer observed. As the gas only comes in contact with the water for a short time, and is not agitated with it, only a very trifling loss of  $\text{CO}_2$  by absorption will occur, and this may be further diminished by employing strong brine instead of water. The nitrometer is now filled with water, some water being also placed in the cup, and the three-way-tap is opened so as to allow the india-rubber tube P to become filled with water, and while this is dropping connection is made with the capillary tube of the measuring vessel. The three-way-tap is then turned so as to open a communication between A and K, the tap M closed and L opened, when the gas will flow from A into K. A few drops of water from A are allowed to follow the gas. E is then closed, some of a concentrated solution of caustic potash poured into the cup, and the three-way-tap opened so as to allow the liquid to flow into the nitrometer, when L is closed. The globular enlargement at K, an arrangement for which I am indebted to Dr. A. H. Elliott, causes the solution to spread as a thin film over the surface of the glass, and insures rapid and perfect absorption of the  $\text{CO}_2$ . In this way the minimum quantity of the reagent can be employed. Practically, absorption is known to be complete by no more reagent being sucked in from the cup, and my experience shows me that the reaction is almost instantaneous. If, however, any doubt exist on this point, all the taps should be closed, and the nitrometer detached and shaken up. The tap M is then re-opened, connection again made between K and A, and the residual gas driven back to the measuring vessel, where its volume is observed, the decrease of course being due to  $\text{CO}_2$  absorbed. The whole manipulation is extremely simple, requiring only a few minutes up to this point. For the absorption of the other gases the same series of manipulations is required, but before proceeding to the next step it is necessary to remove the potash solution from the nitrometer. E being closed this is done by turning the three-way tap so as to establish communication between H and K. M is closed and L opened, and water poured into the cup until the nitrometer is thoroughly flushed out. Then on turning the three-way tap so as to make communication between K and A, and opening E, the gas is again drawn into the nitrometer and is ready for further treatment in the following order:—

a. The  $\text{CO}_2$  having already been absorbed by a strong solution of potash;

b. A saturated solution of bromine in bromide of potassium is introduced to absorb the hydrocarbons of the ethylene series.

c. A little potash is allowed to enter to absorb any bromine vapour, and the free oxygen is then absorbed by an alkaline solution of pyrogallic acid.

d. The nitrometer having been flushed, the carbonic oxide is absorbed by a strong solution of cuprous chloride in hydrochloric acid. The absorption occurs with great facility, and on then running in water through the tap any hydrochloric acid vapour is readily absorbed at the same time that the cuprous solution is washed out.

This completes the possibility of analysis by absorption, and hence the next step is to add oxygen to the residual gas, pass an electric spark, and note the contraction and amount of  $\text{CO}_2$  formed in the usual way, which observations give data for calculating the proportions of hydrogen, marsh-gas, and nitrogen. The measuring tube, parallel tube, and reservoir are practically identical with Stend's arrangement. The method of introducing and using

the re-agents and the employment of the globular enlargement are due to Elliott.

Of course strictly accurate results are not obtainable if water be employed in the measuring tube, but the error due to this cause may be reduced so as in many cases to be practically insignificant if brine be employed instead of water in this part of the apparatus.\*

It is possible to conceive a still simpler form of apparatus by which useful rough analysis of gases might be made. This would be to dispense altogether with the separate measuring tube, and have the nitrometer graduated and furnished with platinum wires.

Perhaps there is no chemical operation more difficult to describe than that of the manipulation with an instrument for the analysis of gases, but in practice the mode of using the apparatus in question will be found exceedingly simple, and to anyone in the habit of working with gases means will readily suggest themselves for increasing the accuracy of the results. These precautions I have purposely omitted, as I have nothing new to say upon them, and my object in bringing the apparatus before the Society of Chemical Industry is to call the attention of its members to a ready means of making technical analyses of gases with a reasonable approach to accuracy, and not to attempt to replace what I may call the standard methods of gas manipulation familiar to all scientific chemists.

FIG. 4.

In conclusion, I may call your attention to some qualitative applications of the nitrometer with a three-way tap, which instrument furnishes an extremely ready means of obtaining certain gases in a state of purity. For instance, if the lower end of a Lunge's nitrometer tube be cut off and the opening closed with a perforated cork fitted with a T-piece, one branch of which is closed by a clip and the other communicates with the reservoir, we have a convenient apparatus for generating at will small quantities of such gases as can be readily evolved without application of heat (Fig. 4). Thus, for example, if some granulated zinc be placed in the nitrometer and the instrument filled with water, on allowing acid to enter through the cup hydrogen perfectly free from air will be evolved, and can be utilised in any manner desired by opening the three-way tap, to which a piece of india-rubber tubing has previously been attached. The T-piece at the bottom enables the dense solution of zinc to be tapped off when desired, and so the apparatus can always be kept full of hydrogen and in order for use. For small quantities of sulphuretted hydrogen the apparatus is also well

\* I find that 100cc. of strong brine at the ordinary temperature dissolve 29.0 cc. of  $\text{CO}_2$ , whereas pure water would dissolve about 100cc. Messrs. Cubley & Preston are prepared to supply the apparatus for gas analysis described in the text.

adapted, and by means of the T-piece any choking up by ferrous sulphate can be wholly avoided. Carbon-dioxide also can readily be generated in the nitrometer tube, and if a small quantity of oxygen be required, as, for instance, in a gas-analysis, it can be obtained instantaneously and in a state of purity by the reaction between acidulated permanganate and peroxide of hydrogen.

It is the three-way tap which renders the nitrometer suitable for a large number of the purposes suggested.

In conducting the numerous experiments of which this paper is the outcome, I have been greatly aided by Mr. J. H. Worrall, to whom my best thanks are due.

#### DISCUSSION.

Professor TILDEN: I think Mr. Allen is to be congratulated on the useful test he has introduced for determining the amount of nitrite in "sweet spirit of nitre," and I think pharmacists will be glad to avail themselves of it. In some earlier experiments of mine, I endeavoured to make use of the well-known decomposition of urea by nitrous acid, which results in the evolution of the whole of the nitrogen of the nitrite together with the nitrogen and carbonic acid from the urea. The relatively large volume of gas thus obtained makes the estimation of small quantities of nitrite possible, and increases the accuracy of the determinations. I venture to suggest to Mr. Allen that he should try this reaction. I feel tempted to criticise the process of gas analysis we have just seen illustrated, but I presume it is not expected to yield accurate results, and would be used only for technical and comparatively rough purposes. Its most serious defect appears to be the very large bulk of the liquid re-agents which is used.

Mr. STAVELEY: I should like to ask Mr. Allen if he has had any experience in the determination of the benzene present in illuminating gas. This has now become a very important point in the gas industry, and especially in the industries which have recently been started for the obtaining of benzene as the principal product in carbonising coal. There have only been two or three analyses of coal gas published in which benzene has been given. One was by Bunsen, and he gave about 1.33, and the other by Berthollet, of Paris gas, in which he gave a very large quantity, amounting to  $3\frac{1}{2}$  or 4 per cent. of benzene. It is very desirable that we should have an exact method of determining this. I believe the method Bunsen followed was to absorb the paraffins by bromine water, and the benzene by fuming sulphuric acid.

#### REPLY.

In reply, Mr. ALLEN said: With regard to the estimation of urea, the production of the apparatus just shown was an illustration of the remark with which I commenced my paper—namely, that various modifications of the nitrometer had doubtless suggested themselves to individual chemists. I have tried the reaction suggested by Dr. Tilden, for the assay of nitrites by treatment with urea, but certainly did not obtain encouraging results, the reaction being too slow. This, however, may have been due to my using an insufficient quantity of acid. But the fact that the gas evolved would be a mixture of nitrogen and carbonic acid, would, in my opinion, be a disadvantage, as it would always necessitate operating over mercury, and hence would do away with the advantages obtained by substituting brine. Respecting the remarks of Dr. Tilden, as to the

loss of soluble gases in working the gas apparatus, I may point out that agitation, under the conditions described, enables one to use the minimum quantity of each re-agent requisite for complete absorption. Literally, to effect the same set of absorptions with Stead's arrangement, the gas would have to be brought in contact with not less than 200 or 400 centimetres of liquid. Unless, therefore, we revert to Bunsen's method of absorption by solid re-agents, the mode of manipulation described by me seems the most free from objection. With regard to the question about the estimation of benzene in coal-gas, I am sorry I am unable to give a definite reply, but would suggest that some method, based on the absorption of benzene and its homologues by fuming nitric acid, would probably be found to answer.

#### PROFESSOR FERGUSON IN THE CHAIR.

### ON THE PROCESSES EMPLOYED IN ITALY FOR THE EXTRACTION OF OILS, ETC., FROM BITUMINOUS ROCKS IN THAT COUNTRY.

BY MR. JAMES MURRIE.

ITALIAN BITUMINOUS DEPOSITS.—The Italians, during the past generation, have, as you are no doubt aware, been making strenuous exertions to develop their internal resources and to occupy a prominent position in the commercial world. So far they have made a most rapid advance in manufacturing for their own requirements, and the public and commercial undertakings initiated and carried out during this period will compare favourably with the advancement made by any other civilised nation.

These results are mainly due to the enlightened and far-seeing legislation of their Government, which, while aiming at making Italy one of the most tolerant and free countries in the world, have held out every inducement and facility to foreigners to embark in their undertakings, or to initiate and develop industries under the surveillance and direction of their own employes, irrespective of nationality. Hence a very great proportion of the works carried

on have been begun and conducted by imported skill and capital; and it may be added that it has been the heavy taxation on this same capital which has been mainly instrumental in placing Italy in its present sound financial position.

Unfortunately for the continued prosperity of the country, it lacks one of the most important agents by which its almost illimitable mineral wealth can be made the most of—namely, a coal-bed. Although possessed of a considerable number of carbonaceous deposits, mainly in the form of lignites, these are either too poor in heating properties, or too limited in quantity to compete with imported sea coal, the cost of which is a heavy tax on the finished products of manufacture. The Italian Government, fully alive to the importance of having reliable data on the various mining operations carried on, have established a corps of engineers, having headquarters in the principal centres, whose duty it is to examine and report on any new bed of mineral, and to give an abstract of the processes in operation. The result is embodied in an annual report, which is published in book form and contains a fairly accurate synopsis of the work done and in progress. To those interested in this department of Italian industry the report in question forms an excellent reference.

Apart from this, there are a considerable number of foreign adventurers or explorers in the country, who are keenly alive to the value of any discovery of any new field of mineral capable of being turned to account commercially, and who, in a majority of cases, are the promoters or indirect means of floating new concerns, in connection with which it cannot be too well known that the country has been explored throughout by Government experts, and, besides, is peopled by a class who know the value of commercial commodities as well as the passing or temporary resident. Any reported discovery cannot therefore be too well scrutinised, even although backed up by scientific reports.

Oil and bituminous indications do occur over a very wide area at different points throughout the country, which have received more or less attention from those interested, and which has given rise to the popular belief that a belt of oil passes through the Apennines in the direction of Roumania, rising to the surface near Bucharest. This theory has received the support of several British geological experts, which, if true, and capable of being extracted on the American system, would undoubtedly prove a great stimulus to Italian industry, and be the means of making Italy the leading nation in the Mediterranean.

The oil and bituminous indications which have received the greatest share of attention are those found in a spur of the Apennines, known as the *Abruzzo*, in the province of Chieti, and about twenty miles inland from the town of Pescara, on the Adriatic. The locality can be determined by a reference to a map: an imaginary line, drawn between Mount Etna in Sicily and Mount Vesuvius at Naples, and continued towards the Adriatic, will pass through the district in question, the exact locality being about 90 kilometres beyond Naples.

The oil indications occur in the form of a flux, or tarry, sandy mass, which exudes from the mountain side after heavy rains, and the bituminous indications in the form of asphaltic rock. The asphaltic deposit I purpose describing more particularly, occurs in the slope of the mountain, dipping into the southern side of the river Pescara, in the vicinity of the town of San Valentino. The minerals of the district consist of broken limestone, sandstone, marl, and clay, gypsum and limestone with indications of sulphur, and the geological formation appertains to the eocene

age. The bituminous rocks occur in two distinct forms—namely, a strictly asphaltic rock, consisting of limestone and earthy matter impregnated with bitumen, the bitumen acting as a cement in holding the body together; a bituminous stone resembling the American prairie oil-stone in appearance, the rock in this case acting as a carrier of the bitumen.

The asphaltic rock is formed on the lower slope of the mountain, rarely at a greater altitude than 2000ft., and the oil-stone, or bituminous stone, invariably at a greater altitude. The asphaltic rock is strictly a superficial deposit, which occurs very irregularly, sometimes in isolated boulders of limestone, but more frequently in surface soil or thin sheets of nearly pure bitumen between the earthy soil and a lower bed of clay. In the case of limestone, the rock usually resembles a foliated clay, or rotten-stone, cemented together by the bitumen, and in a few instances, nearly pure limestone uniformly saturated with the bitumen, the proportion rarely exceeding eleven per cent., and the average about five per cent.

The bituminous stone found at a higher altitude is more uniform in its nature, consisting of calcium and quartz, closely associated with each other, filled with myriads of microscopic cavities, which contain the bitumen. This deposit occurs in veins running parallel with one another in line with the slope of the mountain; the breadth of the vein is very variable, in some cases 10ft., and in others—not one mile apart—100ft. The depth averages 60ft. The proportion of bitumen is more uniform than in the lower deposit, the average being three and a half per cent.

**MANUFACTURE OF PRODUCTS FROM ASPHALTIC ROCK.**—The asphaltic rock is, from its peculiar formation, specially adapted for asphaltic purposes; as such it has been fairly successful, and through the instrumentality of an Ancona merchant, W. von Bremen, has found its way to nearly every part of the globe. The process employed in its preparation corresponds to the kindred operation carried on in the neighbourhood in the preparation of mastic for pavements. The Italian process is essentially as follows:—The rock on being quarried or excavated is conveyed to the factory by means of donkeys, mules, and women, thence is broken up into pieces suitable for passing through the disintegrator or pulveriser, converting the stone into a powder the consistency of finely ground sand, in which condition it flows into a revolving cauldron, maintained at a constant temperature of 400° F., and is there mixed with a proportion of bitumen, the percentage depending on the quality of the rock, and the purpose to which it is to be adapted. For flooring and roofing purposes about 6% is usually added.

After the mixture has been thoroughly agitated, the semi-viscid mass is run into moulds, not unlike a cheese box; on cooling it hardens sufficiently to admit of handling in railway transit, when on reaching its destination and being prepared for use, it is again broken up, re-melted in small boilers, and spread over the flooring or pavement bed, trowel fashion.

It forms a capital roofing material for a warm country; being a good non-conductor, it keeps the chambers cool and refreshing in summer, and effectually excludes moisture from entering in winter. For flooring, again, it prevents damp, and being hard enough at the ordinary temperature to resist abrasion, answers well for many purposes where a clean and dry floor is an important consideration. Its employment as a pavement and cement for reservoirs and canals is too well known to need repetition. In manufacturing paving bricks, the semi-liquid

powder run from the revolving cauldron is conveyed to a hydraulic press, fitted with a series of recesses and dies to stamp the brick into the desired shape; the recesses are made to contain five or six times the capacity of the finished brick, a pressure of about two tons per square inch, applied gradually, being sufficient to give the brick the necessary degree of hardness. A pavement formed of these blocks, made of a neat pattern, say having hexagonal faces, about 6in. in diameter, and about 2½in. thick, presents an exceedingly attractive and artistic appearance, and at the same time excels any other in durability and cleanness. The high cost of manufacture and heavy transport charge has prevented the introduction of these bricks on any large scale, although often met with in the courtyards of the more important Continental cities, particularly Venice, Rome, Florence and Paris. The moist atmosphere of London has prevented its introduction to any extent in that city.

has proved so to several companies who have erected plant with the expectations of extracting the bitumen on the same line as employed elsewhere. This becomes apparent when we consider that to heat the asphaltic rock means melting the cementing or adhesive body; the earthy matter or broken limestone having no longer any tendency to retain its rigidity crumbles up and subsides to the lower part of the vessel, forming a semi-viscid mass of bitumen, soil and gritty limestone, which can neither be strained or separated by mechanical means. While this tendency or action is serviceable in the preparation of mastic, it renders the rock practically useless for the extraction of bitumen.

The only material suited for the extraction of bitumen is the stone found at the higher altitudes, which, depending on the cementing property of the lime to retain its rigidity, can be heated to a comparatively high temperature without disintegrating

FIG. 1.

It may be added that the odour given off in melting and laying bituminous mastic is rather agreeable than otherwise, and forms a striking contrast to the coal-tar asphalt paving operations carried on in this country.

**EXTRACTION OF BITUMEN.**—Closely associated with the preparation of the mastic and forming a companion to it, is the extraction of the bitumen from the rock, either for mixing subsequently with the asphaltic powder already described or for other purposes. The process at first sight seems to be a very simple one, the mineral only having to be heated in a suitable vessel to allow the bitumen to liquify when heated, and descend or flow downwards through the mineral, escaping by a suitable outlet placed in the lowest part of the chamber. In reality, however, the operation is comparatively difficult, and

The effect of heat on this stone—say, 300° F.—leads to the bitumen liquefying and exuding from the minute chambers or cavities in the form of a heavy liquid, having a jet black lustre, which on cooling solidifies to the consistency of solid pitch. A higher heat—say 400° F.—converts part of the bitumen into a semi-oil or tar, and at a still higher temperature decomposition begins.

Several retorts have been devised for extracting the bitumen from the asphaltic rock and bituminous stone; those for treating the former, it may be stated, have been failures, and need not therefore be described; those retorts, again, which have been devised for treating the hard stone have given more or less satisfaction. The most common form is that shown in Fig. 1 and 1A, which essentially consists of wrought-iron cylinders about 7 feet long by 30in. internal

diameter, closed at one end, and placed in an oven with the open end slanting downwards, the angle being just sufficient to allow the bitumen to flow towards the exit formed in the door. Two of these retorts are generally placed in one oven, and several ovens in one bench. The fuel employed is the inferior quality of rock, and the quantity consumed in the furnaces averages one half the quantity treated in the retorts. Each retort contains about 14-wt. of rock, previously broken into pieces the size of a common brick, and the time taken for each charge averages six hours. This form of retort answers fairly well for the bituminous stone, but has failed in extracting bitumen from the asphaltic rock, due to the gritty matters subsiding to the bottom of the retort and forming a barrier to the outward flow of the liquid, which at the same time prevents the heat from penetrating to the interior, a higher heat to

the bottom by a receiver resting on a trolley, and the spent rock subsequently tipped into a small wagon and removed to the furnace by an inclined railway, sufficient carbonaceous matter remaining in the rock to admit of its utilisation in heating the retorts. The average working temperature is 350° F., and the time taken to treat one charge about four hours. The bitumen obtained working with this form of retort is more pure and contains a less percentage of water than any other, and the labour in charging and firing is greatly reduced by the mechanical devices employed.

Ons.—In nearly all cases the companies floated to work this mineral have made the extraction of oil their main point, the heavy duty on imported petroleum, and the great annual consumption of oils for lighting purposes, proving a great attraction in a prospectus. Invariably, or nearly so, these reports

FIG. 1A.

FIG. 2.

effect this causing the formation of a scale, which rapidly leads to the destruction of the retort.

A better designed retort is that of Mons. Bontigny, shown in Fig. 2, which was awarded a silver medal at the Paris Exhibition. The retort is built in an oven, vertically, its main characteristics being the arrangement for preserving the interior of the retort at a uniform temperature; this is accomplished by having an inner vessel, resembling the shell of the retort, but small enough to fit inside, a space being left between the outside of the inner vessel and the inside of the outer shell, to permit a circulation of vapours in the annular space.

The inner vessel contains the rock to be treated, and having its sides perforated, allows any vapours generated to pass into the annular space referred to, and circulating between the two walls, tends to prevent unequal heating. The bitumen is collected at

begin as to the magnitude of the deposit, citing some well-known geological expert as the authority, who, making a flying visit through the valley, has allowed his imagination to outweigh his judgment; further, the ease with which the mineral can be treated, the heavy proportion of beautiful burning oil, and, finally, the immense profits to be made under the invariable judicious management.

The number of companies who have actually erected plant to extract oil from the rock are numerous, and the amount of money sunk in the ventures simply incredible, and with but one issue—total failure and loss of the capital.

The operations have usually been commenced by an attempt to distil the oil from the rock direct in horizontal retorts, in the same way as the Scotch shale before the introduction of the verticals. The result has been failure, which will be evident from

what has been said about extracting the bitumen, the tendency to form a scale in the retort being greatly intensified, which, no matter how carefully fired, rapidly leads to the destruction of the retort, while the quantity of oil obtained after one or two charges dwindled down to about one gallon per ton. The next process has been to extract the bitumen, and subsequently distil it in oil stills, which also has proved a costly process, the bitumen containing a large proportion of water and foreign matter, rendering its distillation by ordinary means a tedious operation and a failure financially: the intermediate process adopted in this country by settling the bitumen and allowing the heavier bodies to subside, being inapplicable, owing to the ebullition of the bitumen at the temperature necessary to ensure precipitation.

ultimate success was that initiated by the late Mr. William MacIvor—long connected with Young's Company at Bathgate—which consisted in distilling the oil from the rock direct by means of superheated steam applied internally.

Mr. MacIvor, who had been appointed by a local company, some ten years previously in existence, to examine into their mineral and report on the best means of extracting marketable products therefrom, after making a number of experiments in extracting oil and bitumen, decided on trying the effect of passing a heated gas through a charge of rock in a small vertical retort, the gas being maintained at the temperature necessary to ensure distillation. The result showed that by employing steam superheated to a temperature of about 600° Fahr., a yield of about 15 gallons per ton could be obtained in about ten

FIG. 3.

The first attempt made to treat the mineral by means of a vertical retort, with the view of extracting oil direct, was initiated by the late Mr. George Bennie, the special retort designed to treat the mineral consisting of an arrangement analogous to the "Boutigny" bitumen retort, the inner vessel being replaced by vertical bars in the form of a wicker basket. The vapours were led off from the top of the retort and condensed in a horizontal condenser. Four retorts were placed in one oven, and the time taken to distil one charge of rock averaged eight hours. This retort, although well adapted for some qualities of the minerals, did not answer for the asphaltic rock, the bars after several months' operations requiring renewal.

Several other forms of retorts were introduced, which, after trial, were discarded; there is no feature of novelty in their design which merits description.

The only process attempted with any prospect of

hours' time; the retort containing about 14 cwt. of mineral. On this basis plant was erected to treat about 200 tons of rock per week, consisting of six vertical retorts having a capacity of about three tons each. The general arrangement is shown in Fig. 3. Each retort had a superheater—Bennie's 2 in. size—and the steam was generated in a steam boiler 14 ft. long by 7 ft. 6 in. in diameter, multitubular type. The condenser consisted of the old style of verticals. Mr. MacIvor unfortunately did not live to see his process carried into practice, and on this account it may not have received justice. Working the full bench of retorts, the yield did not exceed five gallons per ton, further workings showing that a fixed volume of superheated steam, at a temperature of about 600° Fahr., was necessary to ensure distillation of the oil. With the boiler working at its full power, the best result obtained was 12 gallons per ton, with three retorts at work, and the time taken for each charge,

twelve hours. The process so far was a total failure financially. The rock to begin with cost about 10s. per ton for mining and transport, and fuel over 20s. per ton for each ton of mineral treated, thus saddling the crude oil with a first charge of over 2s. 6d. per gallon, the market value of which was under 1s. per gallon. The process, while capable of great modifications, possessed several features which greatly added to the cost of operations, only a very small proportion of the heat in the steam was utilised, the greater proportion escaping in the form of latent heat, which again required a great volume of water to ensure condensation. Loss also occurred in the retort through having to raise the temperature of the rock to distilling point before any oil vapour could escape, the action in the retort consisting of a series of condensations and distillations.

At this stage an attempt was made to simplify the condensing arrangement by simply lowering the temperature of the steam issuing from the outlet pipe sufficiently to precipitate or condense the oil vapour without condensing the steam; close observation showed that the steam, at a temperature of about 300° F., contained only an infinitesimal quantity of oil vapour, clearly proving that the mineral contained no light oils. A second modification was made by enclosing the retort in a jacket formed of bricks, the waste gases from the superheaters winding round the retort before entering the flues. This alteration had the effect of reducing the time of distillation to about eight hours, the full percentage of oil in the rock being obtained, the latter presenting the appearance of having been bleached, and without any bituminous taint. The volume of steam necessary was also, in consequence, reduced about one-third, and the purity of the crude oil superior to that hitherto obtained. Further modifications were brought to a termination through the discovery, at this time, that the company who were carrying on the operations had no more asphaltic rock in their mines, the extent of which was supposed to be so great as to induce the company in question to expend from £50,000 to £80,000 in preparing to begin operations.

This led to a more close examination of the formation of the deposit, the result of which is embodied in the views given further on. The bituminous-stone in the higher grounds was tested with the result that two benches of retorts were erected to extract the bitumen, which was subsequently distilled in the ordinary oil stills, the operation being greatly facilitated by adding a proportion of light oil to the bitumen in the still; this had the effect of cutting up or dissolving the semi-solid mass very rapidly when heated, and thereby allowed the water vapour to ascend freely to the surface, and escape without causing frothing or boiling over.

The oil obtained from the distillation of the bitumen differs greatly in its properties from any other known oil, its most marked characteristics being its unusual density, its freedom from ammonia, scale and spirit, or light oils.

One thousand parts of bitumen distilled and rectified

Yielded.	Sp. gr.	Per cent.	Flash-point.
Burning Oil .....	850	150	139 F.
Intermediate .....	945	339	250
Lubricating .....	990	165	315

The oil obtained from the rock direct, by the superheated steam process, had a density of about 985, 1000 parts of which yielded when distilled and rectified—

Oil under sp. gr.	900	50 parts.
Oil sp. gr.	915	150 "
Intermediate sp. gr.	945	300 "
Lubricating sp. gr.	995	155 "

There are no bye-products. An attempt was made, with fair success, to convert the spent rock into lime, the plan adopted consisting in storing the rock when just drawn from the retort in a mound, and allowed to burn. The residue consisted of a very pure lime, but tainted with a bituminous odour.

So far as the manufacture of oil is concerned, the duty on imported petroleum will never influence the production of burning oil from this asphaltic rock. The density is too great to enable its being employed in petroleum lamps; the heavy percentage of sulphur compounds present also materially adds to the cost of refining, while its complete removal is hardly possible even with careful treatment. The only use to which it can be applied is in street lighting or light-house purposes, where special burners can be introduced for supplying the necessary quantity of air to ensure combustion. Its high flash-point is one recommendation which is more than counterbalanced by the preponderating disadvantages. The intermediate oil is only adapted for cleaning and mixing purposes, its body being equal to the Scotch '803 intermediate.

The lubricating oil makes a splendid lubricant when mixed with a percentage of vegetable or fatty oils; its high density is not an index of its viscosity, the final distillate has a body several times greater than the finest shale oil, but it loses this property very rapidly on being heated, at least in a much greater ratio than in any other known lubricant. It thus demolishes the old saying met with in treatises and pamphlets on oils, that the density of a mineral oil is a safe criterion of its viscosity.

ORIGIN.—It becomes an interesting point to deduce from the formation of this mineral data to enable some notion being formed of its probable origin, and the bearing it has on the supposed oil belt theory.

It is self-evident that a relation exists between the deposits of bituminous rock which have been described under the term of "asphaltic rock," and the harder material under "bituminous stone." The lower deposit, I believe, has simply been formed through the overflow of oil through a higher level; its association with limestone can be accounted for when we consider the effect of an acid in solution on calcium carbonate; the fact of clay forming a break in the downward descent of the oil, likewise shows that the solution has been diverted or prevented from penetrating through non-absorbing material.

The deposit also being superficial and in general mixed with broken limestone and boulders, demonstrates that the latter have found their way from a higher level at a period antecedent to the oil overflow. Then if the stone found at the higher altitudes be closely examined, some other way must account for its formation. The presence of quartz, and the lime being the binding agent, would show that the bitumen has been deposited or secreted in the minute cavities by some other agency than downward percolation. I am inclined to account for its origin by assuming that the vein at one time formed a natural depression in the mountain side, which had become partially silted up afterwards through some subterranean agency; the mountain was subjected to heat, this heat acted on a bed of lignite, other carbonaceous material causing a distillation, the vapours in ascending found vent in this depression, the heavier vapours partially condensing, and the more volatile vapours escaping. It is possible, of course, that the heat acted on a reservoir of oil, perhaps the vein or belt of oil now believed to exist or pass through this identical spot; but to strengthen the supposition that it was a solid carbonaceous body, a layer or bed of lignite crops out of the mountain about twenty miles distant, and it is of course possible to have been a

continuation of the same strata. Even with oil, there seems to me to be no more rational way of accounting for its presence than by assuming that a vast bed of carbonaceous material imbedded in the earth was subjected to heat, which causing contraction, would leave a space for the storage of oil and vapour, the rigidity of the earth at the depth preventing subsidence.

In any case, unless the distilling action is still going on, the oil must, through long ages, have become reduced or exhausted; only a very small proportion could have been caught by the surface soil, the greater volume would find its way into the rivers, and thence to the Adriatic. A close examination of the river banks confirmed this view, and showed also that the period of the overflow was comparatively limited, the indications being confined to one line or strip in the sides of the channel. To still further confirm this supposition, Cicero, in one of his histories, mentions, as a wonder or curiosity of the age, that the river Aternus flowed with blood. The Aternus here spoken of is the same river which flows through the valley to the Adriatic, known now as the river Pescara, and it is very probable that what was supposed to be blood, was really the oil on its way to the sea.

There is evidence in the local archives that oil was sent from the district to Rome, Venice, Turin and Milan for several centuries back. The oil being utilised for street lighting purposes, and the bitumen as a cement for water cisterns. But whether the oil was then distilled from the bitumen or consisted of the natural tar which exuded from the mountain side after heavy rains, is a point I failed to find out.

The indications of oil throughout the country bear a strong resemblance to each other in the low proportion of burning oil and the similarity in properties.

No stronger indications exist in the country than those at the opposite angle of the depression, or basin, about seven miles distant, near a village named Socco Casauria. At the present day a heavy black oil—sp. gr. 950—exudes from the mountain-sides after heavy rains, corresponding in its properties to the oil obtained from the asphaltic rock. Several attempts have been made to strike oil at this spot and in its vicinity, a great impetus having been given to speculation in this direction after the American oil wells were established. In 1863, an Italian gentleman, Maurizio Laschi by name, began operations on a small scale, and ultimately formed a French-Italian company, who erected a refinery and made four trial borings at two different points in the mountain-side, close to the outflow of oil. One well was sunk 1550 feet, a second 510 feet, and the third and fourth about 900 feet each. Oil was obtained at different levels, but in comparatively small quantity, and insufficient to cover working expenses. The operations were conducted by a company of Canadian borers under the direction of an Italian engineer, named Euphemio Ribighini. The altitude of the ground where the borings were made was about 1520 feet above sea level, so that they penetrated about 30 feet beneath the sea line. The following is the result of one distillation of the oil:—

1000 parts sp. gr. 951;	
Oil	= 635
Water	= 29
Residuum	= 222
Gas	= 11

The once run oil on being redistilled and refined gave the following fractionations:—

Boiling Point	Proportion.	Sp. Gr. 60° F.	F. P.	NOTES.
Under 340° F.	0053	78	900°	Clear.
" 100	0079	79	123	—
" 110	0101	80	150	—
" 130	0062	81	177	—
" 115	0078	815	183	Pale Yellow.
" 165	0047	82	203	—
" 180	0072	83	214	—
" 500	0063	84	223	Yellow.
" 320	0062	85	246	—
" 570	0088	865	273	—
Over 570	0068	875	284	Grease.
" 570	0053	890	320	—
Residuum.	0088	—	—	Solid.

The result of this spirited attempt to tap the supposed oil belt was a total failure; the pumps were kept at work for about 18 months, each being wrought in rotation to allow the remainder to recuperate; even then the quantity of oil obtained barely covered cost of fuel and attendants' wages.

The oil was refined and employed in specially constructed lamps for street lighting, the sulphur compounds having been previously partially removed by a treatment with acetate of lead, and subsequent prolonged heating in presence of caustic soda. Oil has also been found at other points in the country, particularly in Veghero, near Rivanazzano. The oil corresponds in its properties to that already mentioned, the density being a shade less, but the odour much more disagreeable, due to the presence of sulphuretted hydrogen. The density of the oil at 60° F. is 915, and the result of treating 1000 parts is as follows:—

Boiling Point.	Proportion.	Density	F. P.	NOTES.
220° F.	100	875	65° F.	Strong Odour.
230	70	88	75	Clear.
240	90	89	85	"
250	93	895	98	"
260	107	90	108	"
270	81	92	114	Yellow Tinge.
280	118	925	117	Yellow.
310	121	93	115	"
Above 310	92	945	136	Dark Yellow.
Do.	53	95	175	Grease.
Residuum.	64	974	200	Solid.

In concluding, it seems to me that further attempts at boring for oil will prove both fruitless and unremunerative. Oil may have existed in quantity at one time; but all the evidence points to the fact that it has been dissipated or dispersed, and it is the remains of the past extensive distillations which is now scattered over the country.

## DISCUSSION.

Mr. HENDERSON: I understand that Mr. Murrie attributes the formation of these bituminous deposits to what is really a case of natural destructive distillation of a bed of lignite. Have any traces of such a bed been discovered, or do the rocks in the neighbourhood of the deposit appear to have been subjected to such heating or metamorphism as would be necessary to produce this alteration in the lignite?

Mr. MURRIE: There is no superficial evidence of the rocks having been subjected to heat at a period corresponding to the time of the supposed oil distillation or overflow. A packet of catclined clay was found in one of the veins of bituminous stone at an altitude of 2800 feet; but its presence could be accounted for in another way. Had it been possible to excavate the vein of bituminous stone to a sufficient depth, I believe evidence would have been obtained to determine with certainty the cause of the bituminous deposit. The bed of lignite, which cropped out in the same range, but about 20 miles distant, probably passed through the district; but the accumulation of *debris* from higher ground hid from view indications of this and other strata, which would, perhaps, have aided in arriving at more definite conclusions. I understand Sigr. Laschi, already referred to, started a factory in the vicinity of Civita-Vecchia, with the view of extracting oils from the lignite found in that district; but I do not know with what results. The oil obtained from the beds of lignite on the Mediterranean side is too dense to be of value in competing with petroleum; it is used for gas-making purposes, and mixing with American petroleum, for street lighting, where special lamps are employed. The more dense oil is refined and mixed with animal and vegetable oils for lubricating purposes, but on a very small scale.

# DESCRIPTION OF A SERIES OF NEW OR IMPROVED THERMOMETERS FOR TAKING HIGH TEMPERATURES.

BY MR. JAMES MURRIE.

At the January meeting, time did not permit my explaining more fully the principles embodied in these new temperature indicators, and the various details of their construction.

The metal mercury, for well-known reasons, has been universally adopted as the best means of obtaining indications of variations of temperature, within certain limits—viz., the freezing and boiling points of the liquid. The freezing point does not require to be considered in this case; and the boiling point under atmospheric pressure is allowed to be 662° F., and near 600° in a vacuum. In the construction of an instrument such as the common mercurial thermometer, it is invariably the custom to exclude atmospheric air from the inner part of the instrument, the space reserved in the stem for the expansion of the mercury being a vacuum, or nearly so. The upward limit of the range of the indicator is thus between 600 and 662° F., depending on the length of the stem, and one or two minor conditions. It is evident that the higher boiling point of the mercury under atmospheric pressure is due to the increased resistance to ebullition; and, reasoning from this, it is evident that by still further increasing the resistance, a greater range of thermometric readings can be obtained. On this principle depends the action of the more important of these heat indicators, virtually being an extension of the ordinary mercurial thermometer.

The most simple means of increasing the resistance to ebullition is obviously the utilisation of the great density of the liquid, in having a vertical column sufficiently long to give the desired pressure on the mercury in the bulb. Another, and perhaps not more difficult way, while it has the advantage of dispensing with the long stem, is in having an elastic fluid, such as nitrogen, in the confined space above the mercury, either in the form of a bulb or elongated chamber, the quantity of the fluid being just sufficient to resist the expansive action of the mercury, and thereby generate an opposite pressure, which is the direct means of raising the boiling point. The glass would, of course, not be adapted for comparatively high temperatures, although suited, if the thermometer be carefully constructed, to indicate temperatures to 750° F. The instrument I have had in use for nearly two months, indicated to 725°, and so far shows no sign of alteration.

For higher temperatures glass would either have to be discarded, or some means taken to preserve the

FIG. 1.

bulb from becoming enlarged or bulging outwards under pressure. Fig. 1 shows one means whereby such an arrangement is adopted, and a glass thermometer, made to indicate temperatures to 850° F. It consists in enveloping the thermometer proper in an outer jacket, formed of two tubes connected near the centre. The bottom tube may be of iron to withstand the action of the heat, and the top tube of glass to enable the movements of the mercury in the inner stem being seen. The annular space is filled

with mercury in the bottom part, and a neutral elastic fluid in the top of the chamber, which is in communication with the thermometer stem. The mercury in the annular space on being heated expands, compresses the elastic fluid in the top part, and at the same time creates an internal pressure equal to and corresponding to the pressure tending to cause distortion, or in other words the outward and inward pressures being equal there is no tendency to alter the form of the central thermometer. The

the one described at the January meeting, the elastic fluid in this case being nitrogen. The indicator tube containing the elastic fluid has a fixed relation to the capacity of the bulb, the aim being to generate sufficient pressure to prevent ebullition without unnecessary strain on the apparatus. By arranging the bore of the tube to contain the necessary volume, and having a clear daylight of 11 in., each inch exactly corresponds to a range of 100° F., the temperature at 1000° F. corresponding to 10 in. on the glass. The

FIG. 2.

glass is maintained in position by a fluted washer, made to embrace the body of the stem. This plan may be applied to the ordinary thermometers, thereby removing the complaint about the zero point not remaining constant, when the instrument was in constant contact with the heated body.

For temperatures above 850° F., it is preferable having the bulb made of iron or steel, as shown in Fig. 2, designed to indicate temperatures up to 1000° F. This instrument is but a modification of

FIG. 3.

bulb is protected from distortion by an arrangement analogous to the more delicate instrument shown on Fig. 1. In this case the bulb alone is jacketed, the annular space being partially filled with mercury, the saturated vapour of which gives the pressure corresponding to that in the minor bulb. The inner or bulb proper is thus free from all tendency to distortion. This form of instrument has been most

severely tested to ascertain the effect of heat and mercury combined on the bulb, and so far has given satisfaction. There are a variety of modifications of this form which do not require special notice, some of which will at once occur to you, such as employing the saturated vapour of ammonia or carbonic acid in the upper chamber. The foregoing apparatus are mainly intended to take indications of temperature with comparative rapidity. The mercury only having to absorb a specific quantity of heat, no time is taken up in generating vapour.

Where the instrument is a fixture, as in the case of an oil still, a rapid indication is of less importance, the temperature of the gases in the vessel taking some time to vary, allows the apparatus time to accommodate itself to the new conditions. In such cases the apparatus may be constructed in a slightly different way. The mercury may be maintained in a liquid

became evident that some other gauge than the Bourdon would have to be adopted if accurate indications were to be obtained. The spring of the gauge when subjected to a comparatively low heat, either lost its elasticity or the expansion of the spring was magnified through the rack and pinion arrangement. For indicating pressures in steam boilers, the Bourdon may be fairly accurate, but it is not adapted for laboratory work, where extreme accuracy is essential. The sketch (Fig. 4) shows a pressure gauge designed as an adjunct to the thermometers, and

FIG. 4.

condition by the pressure of its own vapour, generated in and confined to the bulb, this pressure being measured by a pressure gauge. The arrangement is really based on the same principle as Schaeffer's Tension Thermometer, only the means of carrying out the principle differ very materially. Here it is the bulb alone which is heated, or brought in contact with the heated body. Any vapour generated cannot escape from the bulb, the pressure of which is communicated to the gauge by a column filled with mercury. This arrangement is shown in Fig. 5.

Fig. 3, it may be added, is a combination of the two principles, the expansion of the mercury being shown by a transparent glass tube forming a continuation of the stem, and the pressure of the saturated vapour measured by a Bourdon or own form of gauge. In determining the pressures of the different vapours, it

FIG. 5.

FIG. 6.

which promises to compete with any metal spring gauge, having the advantage in cost, accuracy and sensitiveness. It consists of a glass tube sealed at one end, and having its terminal widely separated by the device of employing a bulb on the extremity of the tube. This tube is filled with an elastic fluid, and its open end dipping into a vessel filled with an opaque liquid. Surrounding this central vessel is an outer chamber, and the annular space filled with a transparent liquid. The instrument on being connected to the generator, and the valve opened has its contents subjected to hydrostatic pressure, which compresses the elastic fluid in the central vessel to the extent shown by the ascent of the opaque liquid, the pressure existing in the generator being shown by an indicator

fixed on the outer casing of the gauge. In practice the instrument has answered well for high pressures, and it has been and is being fitted on steam boilers with satisfactory results.

Figs. 5 and 6 illustrate this form of instrument, with one of these pressure-gauges attached. The bulb can be filled with any fluid which will not act on the mercury or metal forming the bulb, and the pressure of the saturated vapour measured by any known gauge, due allowance being made for the pressure caused by the column of mercury in the stem. Working with mercury alone, temperatures ranging to 1400° F. can be indicated.

FIG. 7.

Another form of apparatus, specially designed for temperatures approaching 2500° F., is that shown in Fig. 7, which is practically a gas thermometer, but possessing one or two features of its own. The gas is maintained at a constant volume in a steel casing or bulb of high melting point, and the pressure measured by a very sensitive gauge of the foregoing design. This bulb is enveloped in an outer casing, the annular space being filled with a fluid which, while preserving the form of the bulb proper, at the same time is made to prevent diffusion of the gas in the central vessel by having an equal or greater pressure than that existing internally. The outer jacket may be surrounded by, or enveloped in, some material

which prevents oxidation, without retarding the motion of the heat. For temperatures under 2000° F. it has answered fairly well in the preliminary trials, and experiments are being made to test its efficiency at still higher temperatures.

These are the most striking forms of these new or improved heat-indicators. To give a description of each design would try your patience, considering that there are over thirty-six forms of the apparatus, the greater number of which are for indicating temperatures up to the softening point of glass. The pressure-gauge, also, can be constructed in twelve different forms, depending on the pressure it is desired to register.

#### DISCUSSION.

Professor MILLS said: I would like to ask Mr. Murrie a question about the thermometer on figure (No. 3) showing the lowest range of temperature. It is well known that in constructing a thermometer the operator heats the stem very strongly, and afterwards drives the mercury up it; the result of it is that where the mercury comes in contact with the hot stem it drives all air before it. At the extreme range of the mercury the thermometer can thus be sealed free from air. The reason for this, of course, that if we have air inside the thermometer, and allow the mercury to move up and down, the air gets between the mercury and the glass, in varying amounts according to temperature. The same objection should apply to nitrogen or other gas. I should like to ask Mr. Murrie if any of these irregularities have been observed, and if it has not been found necessary to get rid of them by some means or the other. Then, again, as regards the sketch on my extreme left (Fig. 6), the bulb of the thermometer is filled with mercury, and is kept from deformation by being surrounded by mercury in another bulb. I suppose for this very high temperature the glass is very thick. The question is, Does the thermometer keep a constant zero, and does the bulb undergo any deformation? Of course the bulb when very strongly heated must become rather soft; and even at lower temperature glass is in fact a plastic substance. At a very high temperature it must become soft, and if thick must tend to float, and ultimately, therefore, become deformed. Of course this is only speculation based upon experience, but I should like to know what happens in both the cases I have mentioned.

In answer to Professor Mills, Mr. MURRIE said: In the glass thermometer indicating to about 800° Fah. a difficulty is experienced in driving out the common air, and replacing it with nitrogen, a trace of oxygen having the effect of forming small specks on the inside of the tube.

Professor MILLS: But does it not get between the mercury and the glass?

Mr. MURRIE: Not so far as I have been able to determine. If the stem of the thermometer be heated at the same time, in the making of the instrument, no gas will adhere to the sides of the tube, and in practice the gas has not found its way between the mercury and the glass. If it did, the effect would be to break up the column of mercury into one or more sections, while my experience is that the employment of an elastic fluid in the upper extremity of the tube prevents this action, and permits the instrument being lowered in temperature with comparative rapidity, without the fear of the column splitting. Regarding Professor Mills' second question on the liability of the metal bulb changing its shape under continued heating: This can hardly take place if fitted with an outer jacket, and working in the way already described. When the instrument was a fixture and subjected to heat for any length of time, I would

depend more on the form of instrument shown on Fig. 3, where the pressure was measured by a gauge, and the corresponding temperature read off. I have made many experiments with a thermometer without the outer jacket, but fitted with an adjustable indicator, and after one or two trials with a new instrument, I found it was not necessary varying the indicator, the metal receding to a fixed point. Of course this was

FIG. 8.

only in taking occasional measurements of temperature, where the instrument would only be a few minutes in contact with the heated body. This instrument is shown on Fig. 8. So far as variation is concerned, the only provision to be guarded against is the expansion of the metal forming the walls of the bulb, but this applies to the ordinary glass thermometer as well, and the variation is so small as to be immaterial.

## Obituary.

### DR. ADRIAN BLAIKIE.

At the early age of 29 years, this promising young chemist passed away on the morning of Saturday, the 7th of February.

Dr. Adrian Blaikie was the fourth son of the Rev. Professor Blaikie, of the New College, Edinburgh. He received his school education in the Edinburgh Academy and Fettes College. When he was eighteen he went to Stuttgart,

where he studied chemistry under Professor von Marx, during two years. Returning to Edinburgh, he entered on the science curriculum in the University, where he successively took the degrees of Bachelor and Doctor of Science. His success as a student is shown by his having been awarded the Baxter Physical Science Scholarship, and the Hope Chemistry Prize, at that time the two highest honours attainable in his special department; and his powers as an original investigator were proved by a series of papers on certain organic compounds of sulphur, the joint work of Professor Crum-Brown and himself, published by the Royal Society of Edinburgh, during the years 1877-9. After holding for one year the post of Lecturer on Chemistry at the University College of Bristol, Dr. Blaikie was appointed by the Government to assist the late Dr. R. Angus Smith in his important duties as the General Government Inspector of Alkali Works. To that work Dr. Blaikie brought skill, industry, and enthusiasm; so that he soon became, not only the official assistant, but the trusted friend of his chief. On the death of Dr. Smith, in May of last year, Dr. Blaikie was promoted in the service to the responsible position of the Inspector of the Tyne district; and in August he entered with ardour upon his new duties in Newcastle. But these were not to last long. Dr. Blaikie had never been very strong; and in the last week of November he was seized with an intermittent fever, which, after a lingering illness, resulted in his death early on Saturday morning, 7th February, at his father's house in Edinburgh. This event has deprived many of a friend, endeared to them by his refined and winning nature, and has cut off a young life of great promise.

## Journal and Patent Literature.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

*Improvements in Apparatus for Purifying and Softening Water for Steam Boilers, Laundry and Other Purposes.*  
H. J. A. Bowers, Acton. Eng. Pat. 481, Jan. 3, 1884.

THE inventor separates the mineral and other impurities from the feed-water before its entry into the boilers, by first conveying it into a large pipe fixed in the steam space of a boiler. This pipe presenting a considerable surface to the steam in the boiler, the temperature of the water passing through approximates closely to that of the steam; the mineral and other impurities, which are liable to form scale or deposit in boilers, are thus rendered insoluble. The feed-water now passes from the pipe into an apparatus called the separator. This consists of two vertical chambers standing upon, and connected with, a lower vessel, which tapers downwards to a small outlet provided with a cock or valve. The feed-water enters at the top of the smaller vertical chamber, passes from thence into the lower vessel, in which the heavier insoluble particles are deposited, and then finds its way into the larger vertical chamber, entering at the lower end. This chamber contains suitable filtering materials, through which the water finally passes in its upward course, previously to its delivery into the boiler. The heavier impurities are drawn off from the lower tapering vessel by means of the blow-off cock or valve.—E. G. C.

*Recent Improvements in Thermometrical Apparatus.*  
*Diag. Polyt. Journ.* 254 [4], pp. 158-161.

THE pyrometer of Tremeschini (*Portfeuille économique des Machines*, 1884, vol. ix. p. 64) measures a rise of temperature by the expansion of a thin platinum foil. On using the apparatus, the scale A, sliding on B (Fig. 1), is placed opposite the zero mark  $\alpha$ . A copper rod H,

surrounded by an iron tube G, is inserted into the space whose temperature is to be taken, and as soon as it has absorbed the necessary heat it is quickly withdrawn by means of a handle K, in such a manner that it faces the platinum foil  $\alpha$ . The latter being fixed to  $c$ , its expansion is transmitted to the lever  $\sigma p$ , which turns the finger  $z$ , and thus indicates the temperature on the scale A.

In the same French journal a description of Trampler's graphite pyrometer is given, which is similar to that known in commerce as Steiale and Hartung's patent.

Ducomet uses fusible alloys for the determination of high temperatures. Between a nut  $z$  and a tube A (Fig. 2), infusible rings, and such fusible at known temperatures of 5mm. height ( $u$  and  $v$ ), are alternately inserted in such a manner as to stretch a spring  $s$ , which is in connection with a transmitting arrangement. By means of the nut  $z$ , the finger is fixed at the zero-mark. If now f. i. rings be used, which fuse at 200°, 400°, and 600°, the rod  $c$  will rise 5, 10 and 15mm. as soon as a temperature has been reached at which the rings fuse. The contrivance, therefore, only shows the highest temperature.

Guichard and Co. describe, in the *Revue industrielle*, 1884, p. 161, a finger-motion for metal-thermometers by means of a spring made of several metals. Such pyrometers are known to be very unreliable.

A. and E. Boulier, of Paris, have improved their water-pyrometer. The water which absorbs heat from the space whose temperature is to be measured, say a furnace flue, runs through the tap H (Fig. 3) into the pipe R,

which is placed in the flue. From here it returns through pipe  $r$  into the receptacle N, where its heat is measured by a thermometer. It then travels through the tap O to the cup K, which is fastened to a beam, and held in equilibrium by a sliding weight T. A pliable rod  $p$  is fixed to the fulcrum of the beam in such a manner that it can first come into contact with the pin G, and then with F, as soon as the beam E swings owing to a decrease of weight at K. If, in consequence of an obstacle in the pipes, or owing to any circumstance the quantity of water entering K decreases,  $p$  and G come into contact, whereby an electrical alarm bell L is set in motion. If the water further decreases,  $p$  also touches the pin F, which causes the weight J to shut off the water at H. The pipe H, and all others conducting water from the flue to N, are covered with a non-conducting substance in order to avoid loss of heat.

R. Fluess, of Berlin (Germ. Pat. No. 26,606, 1883), has patented a maximum and minimum thermometer, in which the bulbs are filled with mercury, whereas the capillary tube contains an alcohol thread which is interrupted by a short mercury thread, which latter serves to

move the indicators. The real thermometrical substance in this case is mercury. If the length of the mercury thread be equal to 10 degrees of the scale, it is evident that the maximum and minimum scale will differ by 10 degrees. Fig. 4 shows such an instrument, whose mercury vessel A is forked for increasing its sensibility. The capillary tube B is filled with alcohol, and ends at the top in an enlargement which holds some air. The mercury thread *c* pushes the minimum mark *n* downwards, and the maximum mark *x* upwards.

According to J. M. Crafts (*American Chem. Journ.* 1884, p. 307), the gradual rise of the zero-point in new thermometers is not caused by the air-pressure, but by the compensation of the tensions in the glass of the thermometer bulb. Thermometers filled with air show the same behaviour as those void of air. It is recommended to heat new instruments for some time at a high temperature before providing them with a scale, and use for fixing high degrees the boiling points of naphthalene ( $218.1^{\circ}$ ) and benzophenon ( $306.1^{\circ}$ ).—S. H.

*Improvements in Filtering Apparatus.* J. F. C. Farquhar, London. Eng. Pat. 3234, February 13, 1884.

THE subject of this invention is improvements in that class of filtering apparatus known under the name of the patentee, and for which former letters patent were granted. In this apparatus the filter bed is placed at the bottom of a cylindrical vessel, the upper surface thereof being scraped off by means of a revolving head carrying a cutter plate so that a clean filtering surface is always preserved; the liquid operated upon being introduced under pressure through a hollow screwed spindle, which at the same time advances the cutter plate before-mentioned. In the present case, whilst preserving the same general form of apparatus, certain modifications are introduced in order to enable the filter to deal more successfully with liquids containing either a large percentage of suspended matter or bodies of a considerable

size. The upper part of the cylinder is made into a settling tank, and a strainer placed between it and the hollow tube—in this case concentric with the screwed spindle—so that the solid matter is in part removed before the liquid is supplied to the filter bed underneath the revolving cutter plate; the filter therefore lasts a much longer time than it otherwise would without such provision. The patentee claims—(1) generally, the modifications as described; (2) the special form of apparatus illustrated in the filed drawing.—C. C. H.

*Improvements in Apparatus for Distilling Liquids, for Purifying Gas, &c.* H. H. Lake, London. Communicated by P. A. Mallett and T. A. Pagniez, Paris. Eng. Pat. 3432, February 16, 1884.

THE ordinary apparatus in use for distilling thick pasty liquids, or those which contain much solid matter, are liable to the objection that deposits take place on their surfaces which cause obstructions in the proper working of the apparatus. The patentees in this case propose to remove such deposits, mechanically, as soon as formed, and for this purpose they construct a still as follows:—A column is built up from a number of segments, a rotating shaft passing through the whole. Trays for the reception of the liquid in its passage through the still are fixed alternately to shell of the column and the rotating shaft; their shape conical, the passage of the liquid being through the centre of the fixed tray and over the lip of the rotating tray. Scrapers keep their upper surfaces clean, and are so shaped that the material flowing on to the fixed tray from the lip of the rotating one is drawn towards the centre and passes through on to the surface of the rotating tray, the scraper running on which is so shaped that the matter is expelled over the edge of the tray on to the next fixed table and so on through the whole apparatus. A modification for liquids of a less viscous character is also described. Baffle plates cause the gas used for the operation to pass through the body of the liquid in bubbles during its passage through the still. The claims are (1) in a dis-

tilling column the combination of the rotating and fixed conical trays and spiral scrapers; (2) the arrangement of the conical scrapers; (3) the modifications as shown for liquids of a less viscous character.—C. C. II.

*Novel Apparatus for Chemical Works.* Dingl. Polyt. Journ. 255 [2], 71.

CH. A. BURGHARDT has patented (D. R. P., No. 29,155, January 24, 1884) a compound condenser with perforated plates, for the recovery of naphtha, benzol, and other solvents used in the caoutchouc industry.

The condenser consists of several circular tubes *a*, connected together to form a long vertical condenser, the tubes are separated by circular perforated plates *b*, which being of greater diameter than the condenser have their outer rims cooled by the water in the outer cylinder *c*. The condenser is thus divided into several chambers. The vapours pass in at *d*, and are drawn through the apparatus by connecting the upper part at *e* with a

ing material laced to a bead or projection formed on the joint surface of the plate; (2) securing the cloths used for filtering to a ring which fits tightly inside the frame portion of the plate, and holding the cloth against the filtering surface of the plate; (3) washing the soluble portions of the material under operation from the residue left in the press by first partially filling the chambers and then forcing the washing liquid through the sides of the unformed cake adhering to the cloths on each side of the chamber. The patentee claims as novel each of the improvements as above specified.—C. C. II.

*Improvements in Filters.* F. B. Hill, New Cross Gate, Surrey. Eng. Pat. 3578, February 19, 1884.

THIS patent is for improvements in water-filtering apparatus. The block of filtering material is placed in the interior of a containing vessel so that a narrow space exists only between it and the walls of the vessel. When

FIG. 1.

FIG. 2.

draught. The condensed liquid flows by means of the tubes *f* and *h* into the receiver *g*.

By erecting the condenser horizontally as in Fig. 2, the condensed liquid collects between the plates *a* by the three tubes *f* in three different states of purity.

A separating filter has been patented by C. Pieper in Berlin (D. R. P., No. 28,086, January 1, 1884). It consists, as shown in Figs. 3 and 4, of a frame *a*, in which vertical walls *b* are placed to support the filtering cloths *c*. The liquid enters the centre of the frame by the tube *d*, and is drawn off from the taps *e*, situated at the top and bottom of the apparatus.—S. II.

*Improvements in Making and Working Filter Presses.* James Pedder, Widnes. Eng. Pat. 3460, February 18, 1884.

THE improvements embodied in this specification are: (1) constructing filter-plates having a roll of flexible joint-

FIG. 3.

FIG. 4.

the surface of the block has become coated, a rapid current of water is admitted through a tube in the upper part of the vessel, the direction of the axis of the pipe being on one side of the vessel, and not radially to the surface of the block; a surging gyrating motion of the water is thus produced in the narrow space which more effectually cleanses the surface of the filtering block. The dirty water is led away by a pipe at the bottom of the apparatus. The claim is a general one covering the construction of the filter as above described.—C. C. II.

*Improvements in Treating Liquid or other Materials to Concentrate and Dry the same, and Apparatus therefor.* J. B. Allott, London. Eng. Pat. 3656, February 20, 1884.

THIS invention has special reference to those appliances in which semi-liquid matter is dried by means of currents

of heated air or gases brought into direct contact with the surface of the material, and is more particularly applicable to materials such as sewage or pail emptyings, which give off offensive odours during treatment. The patentee provides (1) a furnace which is used for heating a boiler or other useful appliance; (2) a pair of regenerative chambers through which the heated air from the boiler can be passed alternately, and which can also be put into communication with the chimney or a flue leading to the evaporating apparatus; (3) the drying vessels of the kind known as "Haresceugh's"; (4) the condensing apparatus; (5) a fan for drawing a current of air through the whole system. The exit pipe from the last piece of apparatus is in communication with the combustion chamber of the furnace. Supposing the dryers to be charged and the furnace in operation, the mode of working is as follows:—The fan is set in motion, and that part of the regenerators which has been previously charged with the heat is open to the air; the current of air passing into the chamber is heated to the temperature of the heated surfaces or nearly so, and being led from thence to the dryers over the surface of the material, takes up the water therefrom. Passing on into the condenser the moisture is removed, and the noxious vapours capable of being so condensed also removed; it is drawn from thence by the fan and forced into the combustion chamber of the furnace, where all gaseous bodies are thoroughly purified by the action of the heat. After doing useful work on a boiler or other useful appliance, the heated air is passed into the cooling chamber of the regenerator, where it gives up its heat to be transferred in its turn in a similar manner to the drying apparatus as first described so soon as the first chamber has cooled below its point of useful effect. The air is finally discharged into a flue leading to a shaft. The claims are (1) the mode of using air for the purpose and in the manner described; (2) using the products of combustion for heating regenerative chambers as described; (3) the combination of the different apparatus described as and for the purpose specified.—C. C. H.

*Improvements in Filtering Apparatus for Gas, Air, Steam, and other Fluids.* E. Capitaine, London. Communicated by Dr. Moeller, Knipferhammer, Germany. Eng. Pat. 3877, February 25, 1884.

THE filtering apparatus consists of a casing holding a frame, on which is disposed the filtering material made from any suitable material, and arranged in the form of pouches projecting into the interior of the casing upon which and the fixed frame it is secured by a movable frame. In some cases the pouches are kept open by a frame in their interiors. A similar apparatus in which the filtering material is arranged in the columnar form, is also described and illustrated. The patentee claims as novel (1) the pouch-like arrangement of the filtering material; (2) the suspension of the filtering media between two frames; (3) the arrangement in a pillar form; (4) maintaining the media in position by means of frames.—C. C. H.

*Improvements in Apparatus for Mixing or Disintegrating Fluids and Semi-Fluid Substances.* R. McNichol and I. Walsh, Manchester. Eng. Pat. 7680, May 14, 1884.

THE apparatus consists of a cylindrical vessel provided on the exterior with a cover, and in the interior with three or more discs, one of which is joined to the cover by a tube, and the remainder to a rod entering the centre of the apparatus. The rims of the latter discs are furnished with slits inclined at right angles to each other in alternate discs. The rapid raising and lowering of the rod forces the material operated on through the inclined slits, thus producing rapid and effectual mixing. The points claimed as novel are (1) the apparatus described and shown in the drawings; (2) the use of diagonal slits in discs for the purpose set forth; (3) the use of the double lid.—C. C. H.

*Apparatus for Moulding Artificial Fuel, etc.* F. Loiseau, Philadelphia, U.S.A. Eng. Pat. 12,202, Sept. 9, 1884.

THIS invention relates to that class of machines in which the granulated pulverised or plastic material is fed to and between revolving cylinders having in their surfaces pockets, which, as the cylinders rotate, coincide with each other to form moulds for the material, the improvements being in the construction of these cylinders, and in the use in the hopper of a certain filling block and feed regulator, whereby the accumulation of the material above the cylinders is prevented, and the amount of material fed to the cylinders readily gauged so as to prevent undue excess.

The figure shows a transverse section of the apparatus. The composition is first stirred and brought to a granulated condition in the upper compartment of the hopper E by the blades of the horizontal shaft I, and when delivered into the lower part of the hopper, it is maintained in this condition by the stirring blades F. Underneath the revolving blades and somewhat above the point of contact of the moulding drums D, a feed regulating device K is suspended. This is composed of a stationary block K¹ and a movable block K². The material is moulded by the cavities in the drums D, and the blocks formed are delivered along an inclined screening chute M, on to the revolving apron beneath.—J. T.

*Improvements in Apparatus for Compressing the Condensable Gases.* S. Pulpett, Westmoors, Knowle. Eng. Pat. 12,543, September 18, 1884.

IN the compression of the condensable gases heat is evolved, and in order to absorb this heat and to secure isothermal compression, a small quantity of the liquefied gas is sometimes injected into the cylinder during a part of the stroke. The present invention is to effect this automatically and in the correct quantity. To carry this into effect, the patentee provides a valve working either with a transverse or rotary motion, actuated intermittently by any suitable mechanism, enclosed in a casing in communication with the condenser in which is stored the liquefied gas. At a certain interval in the stroke the valve opens a passage into the cylinder, and a small portion of the liquefied gas is, by the superior pressure in the condenser, forced into the compression cylinder, and thus by its vapourisation secures the desired cooling effect. The claims are (1) utilising the pressure of the condenser for the purpose specified; (2) the valve for the same purpose moving transversely as shown in the drawings filed; (3) a cylindrical valve having a rotative reciprocating motion for the purpose set forth and described.—C. C. H.

*A Composition for Preventing and Removing Incrustations in Steam and Other Boilers.* Geo. Hles, Weeks Hill, and Thos. Morgan, Oldland, both in county of Gloucester. Eng. Pat. 750, October 2, 1884.

The composition is called Hles and Morgan's Anti-Scrupp or Decrustation Composition, and consists of

Carbonate of Potash .....	10 parts per 100
Sulphate of Potash .....	5    "    "
Chloride of Potash .....	5    "    "
Carbonate of Soda .....	20    "    "
Decoction of Hematoxylin ..	20    "    "
Lime Water .....	30    "    "

It is to be used in the proportion of half a pint per horsepower per six working days of twelve hours each.

—A. R. D.

*Apparatus for Purifying Glycerine and other Substances.* A. M. Clark, London. Communicated by F. H. Houghton, New York. Eng. Pat. 13,925, October 21, 1884.

This invention consists principally in combining a still which receives the impure glycerine with apparatus for supplying steam to such still, with a system of condensers and with an evaporator in which the products of condensation are freed from water.—J. T.

## II.—FUEL AND LIGHT.

*Some Experiments on Mineral Oil Lamps.* By L. Schmelck. Dingl. Polyt. Journ. 255 [1], 39, and [2], 78.

THE author considers the effect of different oils, wicks, and chimneys in relation to some of the modern lamps used for burning mineral oils.

(1.) *Oil and Wick.*—The power with which the oil is drawn up the wick, diminishes as the oil is consumed, owing to the increased friction causing the velocity of the stream of oil to become less. The gradual removal of oil, of course, diminishes the luminosity of the flame, but the diminution is found to vary with the quality of oil employed. As vegetable oil, rape seed for example, is more viscid than the common mineral oil, specially constructed lamps should be used. Bellstein (Dingl. Polyt. Journ. 1883, 250, 169) has shown that the Russian oil, although the heavier, is more readily sucked up by the wick than the corresponding American oil.

The flame of a lamp increases in brilliancy for the first twenty minutes or so, till the lamp has acquired a uniform temperature, it then remains constant for about two hours, then begins slowly to diminish. To remedy this the wick is raised; if raised too high a crust forms on the top of the wick which, by stopping up the pores of the capillary channels, prevents the proper ascent of the oil. The different constituents of the oil appear to be sucked up at different rates. This is shown by a table giving the specific gravity of different oils, after different percentages have been consumed. Other things being equal, the luminosity of a flame depends on the breadth and strength of the wick; with three different kinds of wick, no difference was noticed in the rate at which they absorbed oil. As water prevents the rise of oil in the wick, all wicks should be well dried before use. After a while, a wick is impaired from the stoppage of its capillary tubes by particles of dirt drawn up by the oil in ascending. Experiments with incombustible wicks did not lead to any very satisfactory results. Lamps for preventing the sinking of the level of the oil, as used for vegetable oils, are not to be recommended for mineral oils for domestic purposes; they are used, however, in lighthouses. Dittmar uses in his lamp two wicks, one to supply the oil, the other to burn. The former of these is the stronger and reaches to the bottom of the lamp, the latter is shorter and is surrounded by the other at the top. If both wicks are of the same breadth, twice the quantity of oil is used in the same time. The best form is that known as Dittmar's "Sunburner B," with 15mm. burner.

(2.) *Burner and Chimney.* To obtain the maximum effect a fixed relation must be observed between the

size of the flame and the amount of air admitted. An increase in the height of the chimney, of course, augments the velocity of the stream of air. If the chimney be lengthened without a simultaneous screwing up of the wick, a smaller but relatively brighter flame is produced. A greater current of air may possibly cause the particles of carbon to be a shorter time in the flame.

From a series of experiments with a *Reform burner* and *Kaiser oil* the author shows that the relative increase of brilliancy with a long chimney does not compensate for the diminution in the size of the flame. With a greater current of air, the consumption of the oil is quicker, and the intensity of the illumination less. The shape of the chimney is important. In round burners, and in the cosmos, the chimney causes the flame to contract in size. The fault with this and the Reform burner, which consists of a cosmos burner with a tube for the addition of more air to the interior flame, and for supplying the two sides of the flame with air at the same rate, lies in the chimney. The contraction being always at the same height does not vary with the height of the wick within. Rasch has tried to obviate this difficulty by a mechanical arrangement.

To bring air into the flame, the well-known burning plate is used in French lighthouses, and can be fitted to Dittmar's lamp, "Sunburner A," which is then used without the absorbing wick. In this lamp the chimney is not so contracted as in the cosmos, but has somewhat the shape of the old moderator lamps.

In the *Vulcan-cosmos burner* a large burning plate is used, which necessitates an enlarged chimney; one of these lamps burns one-third as much again of oil as the ordinary cosmos burner. The sinking of the oil so rapidly will therefore cause this flame to lose its brilliancy and intensity quicker than the other.

The *Mittrailleuse burner* burns, under favourable conditions, a little better than the cosmos burner, although the proper flow of oil is somewhat retarded by the metal fastening of the wick.

Amongst burners with flat wicks, the Duplex burner is still the best. It burns, however, 70grm. of oil per hour, about twice as much as a cosmos burner with 10mm. diameter. Both brilliancy and intensity of illumination diminish during burning. Most flat burners have the fault of heating the burner too much.

The greatest intensity of illumination of all lamps is obtained when the oil burns with the greatest flame, and this can be obtained by raising the wick as high as possible without the lamp smoking. In this investigation a modified Bunsen's photometer was used, and the standard light was that of four candles, weighing 396 grammes, and burning 35.9 grammes per hour.—S. R.

*On the Luminosity of Methane.* Lewis T. Wright. Proc. Chem. Soc. [3], 21.

PURE methane was prepared by Gladstone and Tribe's method, by the action of the copper-zinc couple on methyl-iodide. The gas was obtained free from methyl-iodide vapour by passing it through tubes fixed in a horizontal position and packed with copper-zinc, which was kept moistened with alcohol, the alcohol vapour being removed by scrubbing with sulphuric acid. It was burned in a London Argand burner, the chimney of which was fitted with a cap for the purpose of limiting the air-supply to the quantity most favourable to the development of luminosity. The methane flame was compared with a Methven standard burner supplied with eighteen-candle gas—i.e., with a light equal to two sperm Parliamentary candles. The results obtained were—

Rate of consumption per hour corrected to 60° F. and 30" B. cb. ft.	Candles observed.	Candles per 5cb. ft. per hour calculated.
2.78	2.9	5.20
4.46	4.6	5.15

The author will extend his observations to ethane and propane.—W.S.

*Separation of Ammonia from Gaseous Mixtures.* Dingl. Polyt. Journ. 254, 434.

H. WELLSTEIN describes the following process and apparatus for the purpose (Ger. Pat. 28,762, 1883).

The lower bent portion of the tube *h* (Figs. 1 and 2), and the pulsometer *P*, are placed in a due so that the contents may be heated. The gaseous mixture enters the chamber *c* by *a* and leaves by *h*, these tubes being provided with valves as shown in the figure. *F* is a reservoir of dilute sulphuric acid which flows into *c* by way of *h*, and is distributed as shown in the figure. When a

sufficient quantity of the dilute acid has collected in the floor of *c*, the valve in *W* is forced open and the liquid flows to *P*, where it is heated until the vapour tension is sufficient to close the valve and force the liquid by way of *g* to the second reservoir *F*. The circulation is maintained in this way until the sulphuric acid is neutralised by the ammonia, when it is interrupted during the introduction of fresh acid.—C. F. C.

*Improvements in Self-acting Retorts for the distillation of Solid Substances.* B. P. Walker, Birmingham, and J. A. B. Bennet, King's Heath. Eng. Pat. 491, January 3, 1884.

THIS invention relates to retorts constructed in accordance with a previous specification (Eng. Pat. 335, 1883), in which the material to be acted upon is made to traverse the length of the retort by the action of a screw into the threads of which the material is supplied from a hopper. The object of the present invention is to prevent the material from being carried round by the screw through the interposition of obstacles which form stops or detents, it having been found that in distilling certain substances the action of the apparatus is impeded by the adhesiveness of the material at certain stages of the process. Parallel with the propelling screw there is a second screw having the same pitch and direction of threads, the screw being arranged so that its threads shall lie between those of the propelling screw. The inventors also arrange a wheel the circumference of which is formed into cogs to correspond and work with the thread of the second screw. The turning of the screw gives rotation to the wheel, and the cogs clear out any adhering matter which may have been carried round by the screws, the wheel revolving within the walls of a pocket attached to the tube in which the screw revolves.

—D. B.

*Improvements in and Apparatus for the Manufacture of Gas for Lighting, Heating or other Purposes.* Jno. Hy. Johnson. Eng. Pat. 1193, January 10, 1884.

CONISTS: (1) In injecting steam into the incandescent coke left in the retorts after the completion of the ordinary process of gas distillation, thus producing

hydrogen and carbonic oxide. (2) In producing a gas of a higher illuminating power by injecting a liquid hydrocarbon into the coke left in the retort directly after the distillation of coal is completed. The gas produced may be mixed with the ordinary gas or with the water gas, produced as above described, according to requirements. (3) In the oxidation of the carbonic oxide contained in the gas mixture, which is produced in the first operation, to carbonic acid by passing that gas mixture, together with a further quantity of heated steam, through incandescent coke or through refractory materials heated in retorts. The latter operation may be carried out in a separate retort, into, and through which, the gas from the first operation is conveyed. From the gas produced in this manner the carbonic acid is removed by milk of lime, leaving thus pure hydrogen gas for use. The drawings illustrating the retort arrangement for this process are not of special interest.—C. C.

*Improvements in the Treatment of Carbonaceous Substances in Ovens or Furnaces for the Conversion thereof into Combustible and other Products.* II. Stier, Zwickau, Germany. Eng. Pat. 1198, Jan. 10, 1884.

ACCORDING to the present invention the construction of a furnace described by Glaser (Eng. Pat. 1962 of 1883) is made use of for treating carbonaceous substances in such a manner that after the removal of the volatile constituents by distillation, the residue is converted into combustible gas by admission of a regulated supply of air or steam into the incandescent mass, so that the operations of removing the volatile constituents and converting the carbonaceous residue into gas are effected consecutively in the same chamber of the furnace. To convert hydrocarbons such as mineral and other oils into aromatic substances, the hydrocarbons are introduced into the coking chamber filled with incandescent coke, the volatile constituents being condensed and permanent gases formed, whilst the solid residues in combining with the coke render this of a compact and improved quality. Carbonaceous substances such as lignite, peat, bituminous shales, which are not susceptible of coking, are treated in a similar manner, by first distilling from them the more volatile constituents, after which the residue is treated with air and steam for the production of combustible gases, which may be employed either directly for heating the coking chambers or for other purposes.

—D. B.

*Increasing the Illuminating Power of Ordinary Coal-gas.* Wm. Godson Little. Eng. Pat. 1578, Jan. 17, 1884.

DESCRIBES an apparatus for carburetting ordinary coal-gas. The hydrocarbon proposed to be used is creosote oil of 9° to 10° Tw. This is supplied to an evaporating apparatus of hemispherical form (the flat side downwards), in which it is exposed in layers of  $\frac{1}{2}$  in. depth indirectly to the heat of the gas-burner placed beneath it. To moderate the direct action of the heat from the burner on the bottom of the carburetter, a movable sheet-metal screen is interposed between it and the flame. The screen only is heated and communicates the heat to the carburetter. The carburetter is kept supplied with creosote from a reservoir placed above it, from which it flows to the carburetter in the proportion in which it evaporates in the carburetter.—C. C.

*Improved Retort for the Production and Revivification of Animal Charcoal from Bones.* G. Valentine, Liverpool. Eng. Pat. 1669, January 18, 1884.

THIS invention, which consists of a system of cast-iron vertical retorts of improved form and construction, is not suitable for abstraction, as without the assistance of the accompanying drawings it is impossible to explain the mode of working the retorts.—D. B.

*Collecting Explosive Gas in Mines.* A. Shippey, London. Eng. Pat. 1752, January 19, 1884.

THE inventor proposes to place gas-collecting vessels in excavations made in the roofs of mine workings in order

to entrap the lighter and combustible gases, and to connect these vessels with gas-holders at the surface.

—J. T.

*Improvements in the Method of and Apparatus for Preparing and Treating Oils and other like Substances for Industrial Purposes.* Frank Wirth, Frankfurt-on-the-Main. Communication from L. Starck, Mayence. Eng. Pat. 1823, January 21, 1884.

LIQUID hydrocarbons or other oils and fatty substances, resins and bitumens which become liquid at a higher temperature than that of the atmosphere, are converted into a permanent solid form by mixing moss peat having a specific gravity of 0.09 therewith. About 100 parts of the latter mixed with from 400 to 600 parts of crude petroleum produce a fibrous mass which can be subjected to various temperatures in boilers, retorts or chambers, in order to separate the carburetted hydrogen disengaged, a furnace provided with iron or clay retorts laid in a horizontal position being used. This furnace, which has three series of retorts—viz., a central series and a series on each side of it—permits the retorts to be heated to any temperature ranging between 50 and 1800°. The central retorts are surrounded by a wall and are exposed to the direct action of the fire. Through the arch of the inner oven thus formed, the heat passes to the outer ovens, in which are placed the side series of retorts and around which the hot gases play previous to passing into flues which are provided with dampers. Where the temperature is lowest steam is admitted and, by reason of the low temperature, is condensed. Where the temperature is highest, carburetted hydrogen gas is evolved and either converted into lamp-black or mixed with hydrogen to form lighting or heating gas. The hydrogen gas is produced by decomposing steam or water in the central retorts. To produce large quantities of lighting or heating gas it is proposed to add to the moss peat saturated with oil 400 to 600 parts of fine coal. In the preparation of lighting gas, resins or similar substances may be used instead of crude petroleum. The lighting gas is purified by passing it through a mass of peat moss and lime, or gypsum. To bleach lubricating oils produced from crude petroleum the oily peat moss is treated with chloride of lime, the lubricating oil being extracted by steam heated to 250°.—D. B.

*Combined Gas Producer and Steam Boiler.* B. C. Sykes and J. Briggs, Cleckheaton. Eng. Pat. 2709, February 5, 1884.

The inventors surround a gas generator by a water jacket below and a steam space above, the arrangement much resembling an ordinary vertical boiler. The gases produced are drawn off from the upper part of the producer by tubes which pass vertically down through the water space.—J. T.

*Gas Purifier Grids.* H. J. Hadden, London. Communicated by John Calot, Massachusetts, U.S.A. Eng. Pat. 3223, February 13, 1884.

EACH bar of the screen or grid is formed with, practically speaking, linear or very narrow bearings to rest against peripheries of each of the holes for supporting it, the bar being between such bearings without contact with the periphery or broadway of the hole; that is, the edges only of the bars touch the holes in the supports.—J. T.

*Improvements in Carbonising Coal.* J. G. Willans, London. Eng. Pat. 3520, February 18, 1884.

THIS invention relates to the carbonising of coal in gas retorts or in coke ovens. It consists in causing the vapour of water to be disseminated through the coal during the heat. A substance containing water is either placed underneath the coal or is mixed with it. In either case the water will be vapourised and disseminated through the coal during the heat. The substance employed may be slaked lime or other mineral substance containing combined or included water, or it may be a carboniferous substance such as moist or wet peat, or wet coal dust.—J. T.

*Improvements in the Methods of Taking off the Volatile Products from Coal, Shale and other Hydrocarbons during the Process of Distillation.* W. A. Byrom, Wigan and J. A. B. Bennett, King's Heath. Eng. Pat. 3736, February 22, 1884.

THE object of this invention consists in removing from the retorts the various products of distillation, and thus preventing them from mixing and avoiding the subsequent expense of redistillation. A retort similar to that patented by Walker and Bennett is employed. In this retort a number of apertures are placed in a line along the highest part of the retort, and arranged in such positions as to be able to withdraw the products immediately they are liberated. This is effected by supplying each exit pipe with a bend of any suitable form, so that the pipe may ultimately be either inclined downwards or preferably point vertically downwards near the side of the retort, the exit pipe being of sufficient length to secure the condensation of the liquid portion of the distillate. The latter runs down the exit pipe and falls into a receiver, whilst for the removal of the gas each exit pipe is furnished with a lateral opening above the point where it enters the receiver. These openings are connected with a horizontal pipe through which the gas is drawn off by means of an exhausting apparatus.—D. B.

*Improvements in Method of and Apparatus for Washing and Purifying Coal-gas.* J. F. Belfield, Exeter. Eng. Pat. 3570, February 25, 1884.

THE apparatus consists of a series of horizontal trays, containing water, and having concentric rings of pegs. Above these trays are revolving discs with pegs on their under sides, alternating with those in the trays. The discs are rotated by an arrangement of levers and movable weight, and secondary steelyard adjustment for regulating back pressure.—S. R.

*Producing and Burning Gas for Heating Purposes.* L. D. York, Portsmouth, Ohio, U.S.A. Eng. Pat. 3393, February 26, 1884.

THE gas generators are worked in pairs. Each is provided with a grate and closed ash-pit, and the two are connected above by a short flue, into which opens a small steam pipe. Air is forced beneath each grate alternately, and the gas produced is taken off below each grate alternately. Thus, the gas produced in the generator receiving air is passed downwards through the fuel in the other producer; and during the passage of the gas from one to the other, more or less steam is introduced by the pipe mentioned above.—J. T.

*Condensing Apparatus for Purifying Coal-gas.* W. T. Walker, London. Eng. Pat. 3987, February 26, 1884.

THIS invention relates to improvements in Walker's annular condenser (Eng. Pat. 545, 1880). The inner and outer condensing cylinders are so made that the space between them is conical, the narrower part being upwards to prevent the deposition of naphthalene between the cylinders. Large tar outlets are made direct through the bottom closures of the spaces between the cylinders. The bottom closures of the cylinders are inclined down to the tar passages. The cooling of the cylinders is effected by means of annular troughs placed at the upper part of the cylinders, with a filling of thick felt (or equivalent porous material) between these troughs and the surfaces of the cylinders; and through this felt the water percolates, and is distributed evenly over the whole surface of the cylinders.—J. T.

*Apparatus for Carburetting Air.* J. H. Johnson, London. Communicated by E. D. Deboutteville and L. P. C. Mahandin, Fontaine le Bourg, France. Eng. Pat. 6652, February 26, 1884.

THE apparatus consists of a vessel, preferably of cylindrical form, for containing the liquid hydrocarbon, divided internally by pendant vertical partitions, extending to within a short distance from the bottom, and preferably arranged in the form of a double spiral. The lower edges

of these partitions are immersed in the liquid, and air is admitted at one side of the apparatus, and is compelled to follow the convolutions of the passages formed by the partitions, till it reaches the centre of the vessel, and then flows in the opposite direction to the outlet. Thus, the air is brought into contact with an extensive surface of the liquid hydrocarbon, whereby it is carburetted under very favourable conditions.—J. T.

*Improvements in Gas Producers of the Siemens Type.* James McFarlane, Motherwell. Eng. Pat. 4075, February 28, 1884.

By means of these improvements small coal or dross can be utilised in gas producers of the Siemens type, thus enabling such gas producers to yield a larger quantity of gas in a given time. The gas producers are constructed with an enclosed hollow bottom, underneath the bottom proper. Passages in the hollow bottom are connected with perforations in the bottom proper, and with side openings around the bottom. Air, or a mixture of steam and air, is injected by means of a steam blower through these passages into the small coal, and so converts it into gas.—S. R.

*An Improved Method of Utilising the Waste Residues of Fuel.* Eng. Pat. 4698, March 11, 1884.

NINE hectolitres of the waste are thoroughly mixed with a hectolitre of fine black coal, and nine litres of coal-tar, diluted with one litre of ordinary petroleum, are poured upon the mixture; after well stirring, a solution, containing 0.75 kilogrammes of calcined carbonate of sodium (dissolved in from 15 to 20 litres of water) is added, to form an emulsion, from which cakes are formed and dried.—S. R.

*Improvements in the Process of Manufacturing Hydrocarbon Gas.* E. A. Brydges, Berlin. Eng. Pat. 6455, April 17, 1884.

THE object of this invention is to cheaply obtain an illuminating gas, pure and free from oxygen and carbonic acid gas. Superheated steam is passed over heated lime, to absorb oxygen and carbonic oxide; then over finely divided iron or copper; and finally over charcoal, to remove the last traces. The hydrogen so obtained is mixed with a liquid hydrocarbon, and then passed through a heating coil, which converts the mixture into a fixed gas. The gas is purified by passing through a washer and chamber supplied with hydrate of lime, ammoniac and water, or other suitable cleansing solution.—S. R.

*Manufacture of Illuminating or Heating Gas and Apparatus for the same.* A. J. Boulton. Eng. Pat. 9084, June 17, 1884.

THE generating and fixing chambers are heated, the one by the combustion of the fuel, the other by the products from such fuel. Steam is decomposed in the fuel, hydrocarbons are added, and the mixture fixed by passage through part of the heated material. Successive volumes of the gas are passed through succeeding parts of the heated material, thus preventing destructive decomposition of the hydrocarbons, and ensuring a gas of uniform candle power. To effect this, two generating chambers are used and operated reciprocally, the superheated steam being passed alternately down into one, and the resulting gases up through the other. The coal is also distilled alternately in the two chambers. The steam is decomposed by passing first through a bed of heated iron scrap, and then through the incandescent fuel. The oxidised scrap is reduced by subjecting it to the action of nascent carbonic oxide, which, in company with the other waste products of combustion, is passed up the superheating and decomposing chambers. Since this is reversible, the scrap can be used repeatedly without removal from the apparatus.—S. R.

*Improvements in and connected with Retorts for obtaining from Coal or other Carbonaceous Substances Illuminating or Heating Gas, Oil, Coke and other Products.* J. Hislop, Glasgow. Eng. Pat. 12,912, September 29, 1884.

THE inventor employs fireclay retorts formed of one or more large pieces, or being wholly or partly built up of firebricks. The retorts are of oblong form in horizontal section, each having a passage formed down the inside of it by a small partition built near one of the narrow sides. The sides of the partition being perforated, the gas generated at any part of the retort has immediate access into the side passage. The latter communicates by a number of horizontal branch pipes with an external vertical pipe, which is, at its top, connected with a pipe leading from the top of the retort to the gas main, condensers and separating apparatus. On the outer side of the vertical pipe, and opposite the branch pipes, nozzles are fitted, provided with plugs, to facilitate the clearing of the horizontal connecting pipes. The retorts are arranged in various ways in connection with ordinary furnaces. A furnace may, for instance, be arranged to a set of four retorts, communicating directly with the bottom ends of the retorts, these bottom ends being nearly horizontal, and having short horizontal outlet parts, extending through the side walls of the building for the discharge of the coke or residues.—D. B.

*Hydrocarbon Furnaces.* H. J. Haddan, London. Communicated by A. N. Leet and E. Neumann, New Jersey, U.S.A. Eng. Pat. 13,948, October 21, 1884.

PETROLEUM or hydrocarbon liquid is often used as a source of heat in steam generators. The present invention does not require any change in the construction of the ordinary combustion chamber, where solid fuel has been employed. On the usual firegrate is placed a shallow pan of iron with open top, which is kept supplied with petroleum. In front of the tank is placed a series of horizontal jets, supplied with steam by the boiler itself, or from a supplementary source when commencing work. The hydrocarbon is ignited, and by means of the jets of steam the flame is spread, a large quantity of air is caused to rush in from below, and the flame becomes very powerful.—J. T.

*Improvements in the Manufacture of Gas.* W. L. Reddie, London. Communicated by R. A. Chesebrough, New York. Eng. Pat. 14,260, October 28, 1884.

THIS invention consists in a improvement in the manufacture of gas, by subjecting bone-black charged with oily or hydro-carbonaceous matter, to a heat sufficient to vapourise the hydro-carbonaceous matter, and convert it into a permanent gas. A vertical retort is employed, provided with a hopper at the top, and a feed roller; inside are sloping shelves, down which the bone-black is supposed to pass gradually to an exit port at the bottom, which leads into a cooler. At the top of the retort is an outlet for the permanent gases formed. A second form of retort is a spiral tube, down which the bone-black is supposed to be capable of passing.—J. T.

*Improvements in Self-sealing Mouthpieces and Lids for Retorts, Stills, and Generators employed in the Production of Gas from Coal and other Substances, and for the Distillation of Chemical and other Liquids.* S. Adams, London. Eng. Pat. 15,447, November 24, 1884.

THIS invention consists of a collar or pad forming a seal made of pure asbestos, spun or plaited into square or round cord, the collar being inserted in a dovetail or elongated groove, either in the face of the lid or mouthpiece, as may be required. It is also claimed to cover the core of asbestos with fine metal wire, to protect the fibres from being drawn from the collar by adhering to the lid or mouthpiece when the lid is opened.—D. B.

### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

*Preparation of Pure Thiophene.* Victor Meyer. *Berichte*, 17, 2641.

THE preparation of crude thiophene—that is to say, a mixture of about equal parts of benzene and thiophene—does not offer any difficulties, whereas that of pure thiophene is a laborious operation, and is often accompanied by loss of material.

By limiting the quantity of sulphuric acid used in extracting the thiophene, no benzene is dissolved. The thiophene sulphonic acid, obtained in this way, gives, on distillation, chemically pure thiophene. Should even a portion of the thiophene remain behind in the benzene, the advantage of the method counterbalances any loss from this cause.

These experiments were conducted on the large scale, but the process is not to be recommended for laboratory use. 2000kilos. of pure benzene boiling within half a degree were agitated for six hours, with 100kilos. concentrated sulphuric acid, and the black layer of acid, amounting to 90kilos., separated. 20kilos. of this were converted into the lead salt, and 3.2kilos. of the crude salt obtained gave on distillation with sal ammoniac chemically pure thiophene. 135grm. thiophene were obtained from every kilogram of lead salt. An analysis of the product indicated the total absence of even traces of benzene. It is important not to add water directly to the black layer of acid, as in this case it completely carbonises on standing. From the author's experiments the following quantities are recommended for obtaining an absolutely pure product: 400kilos. benzene, to be shaken for two hours with 16kilos. sulphuric acid. The black mass is then converted into the lead salt, the lead precipitated with sulphureted hydrogen, and the acid treated with ammonia to obtain the ammonia salt, and finally distilled.—J. B. C.

*Nitrification of Thiophene.* Victor Meyer and O. Stadler. *Berichte*, 17, 2648.

SINCE the discovery of thiophene, attempts have been made to nitrify this substance, and thus to show its analogy with the benzene derivatives. After many unsuccessful efforts, the desired result was obtained by passing a current of air saturated with thiophene through fuming nitric acid. Mononitro-thiophene possesses properties more analogous to paranitro-toluene than to nitro-benzene. It has the characteristic smell of nitro-benzene and nitro-toluene, boils at 224–225° C., and melts at 44°. With fuming nitric acid, it is converted into binitro-thiophene. Binitro-thiophene melts at 52°, and boils at 290°. An isomeric binitro compound may also be obtained from the crude product, crystallising on needles, and melting at 75–76° C.—J. B. C.

*Acetothionone and its Derivatives.* A. Peter. *Berichte*, 17, 2643.

THE method of Friedel and Crafts may be employed in the case of thiophene. This has been demonstrated by Conroy, who obtained phenylthiénylketone. The author, working in the same direction, prepared the acetyl derivative. To 20grm. crude thiophene (50 per cent.), and 92gm. acetyl chloride, 15grm. aluminium chloride are slowly added, quantities of hydrochloric acid being evolved. The yield is not so satisfactory as that obtained by first dissolving the thiophene and acetyl-chloride in petroleum ether, before adding aluminium chloride. Repeated agitation of the mass during the reaction is desirable. When on the addition of aluminium chloride no further evolution of HCl occurs, the reaction is at an end, the petroleum is poured off, the product warmed and poured into water. It separates out as a heavy dark coloured oil. After shaking out with ether, the petroleum previously separated is added. The whole is washed with soda and distilled. After the ether has come over, the heavy liquid is directly distilled, shaken with soda solution and again fractionated. Acetothionone or

methylthiénylketone  $C_8H_5S-CO-CH_3$  is a colourless oil, resembling acetophenone in smell, and boiling at 213.5° C. It combines with hydroxylamine, forming thiénylmethylacetoxime, and with phenylhydrazine, a crystalline yellow compound being obtained. By the oxidation of acetothionones with an alkaline solution of potassium permanganate, an acid having the constitution  $C_8H_5SCOOH$  is obtained. Acetothionone may be nitrified by allowing it to drop into fuming nitric acid cooled to 8°. The product consists of two isomeric mononitro acetothionones, which may be separated by fractional crystallisation from ether and alcohol.—J. B. C.

*Quinoline from Coal-Tar.* M. C. Traub and C. Schärger. *Berichte*, 17, 2618.

ONE of the authors in a former paper prepared a phthalic acid derivative of quinoline, which was shown by Jacobsen and Reimer (*Berichte*, 16, 2602) to be a quinaldine derivative. The authors have experimented with quinolines from different sources, which did not give this derivative. With a view to discovering the cause of this difference, various reactions were tried. They found that by treating quinoline from coal-tar with phosphorus pentoxide on the water bath, an intense red colouration is produced, and by diluting the product with water or alcohol, the solution gives a beautiful greenish yellow fluorescence little inferior to that of fluoresceine. Neither quinoline prepared by Skraup's method nor quinaldine give analogous reactions. The different fractions from coal-tar give dissimilar results. A distillate under 200° behaves like pure quinoline, that under 230° gives a faint reaction, whereas the portion distilling at 235° produces the most intense fluorescence. Above 235° the reaction is faint. This method of treatment with phosphorus pentoxide is a useful means of rapidly detecting a coal-tar quinoline, and gives reason to believe that in addition to quinoline and quinaldine, a third body is present in this fraction of the coal-tar bases, the isolation of which the authors purpose to attempt.—J. B. C.

*Monobromoparaxylylene.* P. Jannasch. *Berichte*, 17, 2709.

IN consequence of a paper by O. Jacobsen (*Berichte*, 17, 2379), stating monobromoparaxylylene to be a liquid not solidifying in a freezing mixture, contrary to the observations previously made by Fittig and the author, the latter prepared the pure compound from pure paraxylylene and bromine in the cold. The product thus obtained boiled at 199–201°, and solidifying in a freezing mixture to a crystalline mass, melting at 9–10°, thus confirming the author's previous observations.—J. B. C.

### IV.—COLOURING MATTERS AND DYES.

*Method for the Preparation of Naphthylamine Compounds.* Dingl. Polyt. Journ. 1884, vol. 254, p. 232.

IN order to replace the hydroxyl group of the naphthyl compounds of the  $\beta$  series by the amido group, a pressure of 30 to 40 atmospheres is necessary in the methods at present adopted. In order to avoid this, L. Landshoff, of Berlin (*Ger. Pat.* 27,378, January 23, 1883), proposes the following method: The alkaline salts of the  $\beta$ -naphthol sulphonic acids are, at a temperature of 200 to 250°, subjected to the action of gaseous ammonia, the latter being passed over them in a slow current for about 12 hours. The following formulae explain the reaction which takes place:—

This method is applicable to all known sulphonic acids of  $\beta$ -naphthol. The alkaline salts of the  $\beta$ -naphthylamine sulphonic acids thus obtained, when converted into the diazo-compounds, and combined with amines, phenols, oxyphenols, naphthols, or their ethers and sulphonic acids in the well-known manner, form colouring matters

varying in the phenol series from yellow to orange and brown, in the  $\alpha$ -naphthol series from red to bluish violet, and in the  $\beta$ -naphthol series from yellow orange to red orange.—F. M.

*On the Preparation of Isatin.* Dingl. Polyt. Journ. 1884, vol. 254, p. 232.

ACCORDING to a patent (No. 27,979, December 22, 1883) taken out by F. Bayer and Co., of Elberfeld, the direct melting together of dichloroacetic acid and analogous compounds, with amines of the aromatic group, is only to be recommended in case of the less reactive amines. When the more reactive amines, such as aniline, toluidine, phenylenediamine, etc., are used, the reaction, even on the water-bath, proceeds so violently, that valueless resinous products are chiefly obtained. In such cases the reaction should be made to take place in solution, alcohol, benzene, etc., being used as solvents. In order to increase the yield of isatin which, when the product of the reaction is worked up directly, is only small, the latter is previously subjected to a process of oxidation. This may be accomplished by passing a current of air through the solution of the product, or by keeping it exposed to the atmosphere, whereby crystals or crystalline masses of almost pure imesatin separate out. This body, which forms the intermediate product in the preparation of isatin, has been found, by careful researches, not to be the original chief constituent of the product of the reaction, but to be formed by the spontaneous oxidation which takes place during the reaction and the purifying process in a more or less imperfect degree. Imesatin and its substitution products are, therefore, obtained in larger quantities by more complete oxidation, as in the manner above described. Instead of the derivatives of the disubstituted acetic acids, the amides and aldehydes, also their alkaline salts and ethers, may be employed.—F. M.

*On Malachite Green.* Dingl. Polyt. Journ. 1884, vol. 254, p. 316. (Ger. Pat. 27,275, September 15, 1883. Dittler and Co., Griesheim, near Frankfurt-on-the-Maine.)

By adding chloride of lime to an acidulated aqueous solution of a salt of malachite green, bluish-green colouring matters are formed. 25kilos. of the oxalate of tetramethyl-diamidodiphenyl-carbinol are dissolved in 1000 litres of cold water, and acidulated with 50kilos. of acetic acid. To the solution 7kilos. of chloride of lime are quickly added under stirring, the whole being allowed to stand for half an hour. From the filtered liquor the colouring matter is separated by the addition of ammonia, dissolved in hydrochloric acid, and precipitated again with common salt. By using a larger quantity of chloride of lime (20kilos.) a colouring matter of a bluer tinge is obtained. An analogous product is formed by employing a solution of bromine in caustic soda instead of chloride of lime. To a solution of 53kilos. of malachite green (oxalate) in 2000 litres of water, 100kilos. of hydrochloric acid, and then 18kilos. of bromine dissolved in caustic soda, are added, the colouring matter being immediately afterwards precipitated by means of ammonia. The colour base thus obtained forms a bronze coloured mass; its salts dye bluish green shades. By increasing the quantity of bromine used the shade becomes bluer, as in the previous process. The salts of tetraethyl-diamido-triphenyl-carbinol behave in a similar manner, but yield more yellow shades.—F. M.

*Method for the Manufacture of Dinitrophenol Sulphonate Acid.* Dingl. Polyt. Journ. 1884, vol. 254, p. 356. (Ger. Pat. 27,271, June 8, 1883. Beyer and Kegel, Lindenau-Leipzig.)

By boiling potassium nononitro-phenol-parasulphonate (obtained from potassium phenol-parasulphonate) with dilute nitric acid, until no more gases are given off, a salt is obtained which in acid solution possesses a yellow colour. The same colouring matter is obtained by boiling

potassium phenol-para-sulphonate with nitric acid in excess:

The potassium salts of phenol-orthosulphonic acid or mono-nitrophenol-orthosulphonic acid by the same treatment yield an isomeric body dyeing similar shades to the para-compound, but being more soluble in water than the latter. The same colouring matter is obtained from potassium phenol-disulphonate by treatment with moderately dilute nitric acid. Instead of the potassium salts of the phenolsulphonic acids, their sodium, magnesium or calcium salts may be used. The sulphonic acids may either be used single or mixed to obtain the same colouring matters. Instead of boiling with dilute nitric acid, the phenolsulphonic acids or their salts may be treated with strong nitric acid, or a nitric acid mixture in the cold, the reaction being completed by subsequent heating. Diazo-benzene-parasulphonic acid which, on boiling with water, yields phenol-parasulphonic acid, by being heated with dilute nitric acid naturally forms the same body as phenol-parasulphonic acid, and diazo-benzene-disulphonic acid, derived from ordinary aniline disulphonic acid, the same body as phenol-disulphonic acid.—F. M.

*Nitround Amido Derivatives of Metaxylene.* E. Grevingk. Berichte, 15, 2422.

By nitrating metaxylene with nitric acid, Fittig obtained a dinitroxylylene (m.p. 93° C.). By employing a mixture of sulphuric and nitric acids, the author obtained in addition to the one melting at 93° C., a dinitro compound of melting point 82° C. 100grm. pure metaxylene, 700grm. sulphuric acid 56° Bc., and 300grm. nitric acid 48° Bc., are brought together and surrounded by a freezing mixture, the temperature being maintained between 3 and 6° C. By varying the quantities of nitric and sulphuric acids, a mixed product of the two dinitro bodies is invariably produced, though in different proportions; and an increase in temperature occasions the formation of a trinitro compound. The two dinitroxylenes are best separated by fractional crystallisation, from alcohol or glacial acetic acid, that of m.p. 82° C. being very much more soluble than that of m.p. 93° C. The operation is, however, a very tedious one, repeated recrystallisations being necessary in order to ensure complete separation. Both dinitroxylenes, on treatment with a mixture of  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$ , give the same trinitroxylylene of m.p. 176° C., first prepared by Fittig. If the trinitroxylylene of Fittig has the methyl and nitro groups in the positions 1:3:2:4:6, then it follows that the two dinitroxylenes must have the constitutions 1:3:4:6 and 1:3:4:2 respectively.

*Metanitroxylidine* 1:3:4:2 dinitroxylylene m.p. 93° C., gives a nitroxylidine m.p. 123°, crystallising in deep red compact crystals. From the dinitro compound of m.p. 82° C., by reduction with  $\text{H}_2\text{S}$  in alcoholic ammonia solution, a totally distinct amido body was formed, melting at 78°, and crystallising from petroleum spirit and water, in golden needles, liquids in which the first xylidine is almost insoluble.

*Metadiamidometaxylene* 1:3:4:6. By reduction of nitroxylidine m.p. 123° C. with stannous chloride and hydrochloric acid, and precipitation of the tin by  $\text{H}_2\text{S}$ , an almost colourless diamine salt is obtained. This gives the free base in the form of a brown mass, from which the pure compound (m.p. 104° C.) can be prepared by sublimation in colourless crystals. It is identical with the base obtained from dinitroxylylene m.p. 93° C.; and by nitrification and reduction with the 1:3:4 xylidine of Nörling and Collin. The hydrochloride gives, with sodium nitrite, a Bismarck brown.

*Metadiamidometaxylene* 1:3:4:2 is prepared by the reduction of nitroxylidine m.p. 78° C., and crystallises in colourless needles m.p. 64°. In this case tin and hydrochloric acid were employed in preference to the chloride, and a modified method of purification was necessary. The colour reactions with sodium nitrite showed that this compound is likewise a metaxylene.

*Triamidometaxylene* is prepared from the trinitroxylylene m.p. 176°, by reduction, and is purified by sublimation. By diazotising the hydrochlorides of the amines with

sodium nitrite, yellowish brown colouring matters are obtained, which impart to silk, in a soap bath, various shades of brown. That from diamine, m.p. 64°, gives a red brown, that of m.p. 104° a yellow brown, and from the triamine a grey olive. With diazobenzene-sulphonic acid different colours are formed. Light yellowish red from the first, a deeper shade of the same colour from the second, and a dark red from the triamine. Dyed on silk, the shades from these varied in exactly the contrary order, that from the triamine giving the lightest, that from diamine m.p. 64° the deepest shade. Metaxylylidine 1:3:4 gives, on nitrication, at low temperature, two nitroxylylides of m.p. 123° and 78°, identical with the two already described. By eliminating the amido group from the two latter, with ethyl nitrite in a sulphuric acid solution, two nitrometaxylenes are obtained, that from nitroxylylidine m.p. 123°C., boiled at 238°C., identical, therefore, with Tawillbarow and Harmsen's nitroxylylene 1:3:4; the second, from nitroxylylidine, m.p. 78°C., gave a nitroxylylene of b.p. 225°C., which must possess the constitution 1:3:2. From metanitroxylylene, a metaxylylidine, 1:3:4, was prepared by reduction, b.p. 215°C., identical with that of Hofmann and Schmitz; and from nitrometaxylylene, a xylylidine of b.p. 214.5°, and of constitution 1:3:2.

—J. B. C.

*Process for the Manufacture of Naphthol-green.* Dingl. Polytechn. Journ. 254 [4], p. 184.

THE Frankfurt aniline dye works of Gans and Co. (Ger. Pat. 28,065, 1884) dissolve 27½ kg. of sodium nitroso-β-naphthol-monosulphonate in 100 litres of water, and after cooling, add 20 litres of iron perchloride solution, containing 5 kg. FeCl<sub>3</sub>. After allowing to stand at rest for some hours, the iron in excess is removed by the addition of an alkali. The mass is filtered, and the green filtrate evaporated to dryness. To obtain the green dyestuff in a pure state it must be either recrystallised out of dilute alcohol, or precipitated from its alkaline solution with a lead salt; the precipitated lead compound is then decomposed with dilute sulphuric acid. In place of Schaeffer's monosulphonic acid, all other naphtholsulphonic acids may be used, save β-naphthol-α-monosulphonic acid and β-naphthol-γ-disulphonic acid. If iron is replaced by an equivalent quantity of cobalt salt, brown dyestuffs are obtained; nickel yields a yellow dyestuff. All these substances belong to that still little known class of organic compounds containing metals, which dye wool and silk in an acidulated solution. An excess of acid causes the disappearance of the dye, which reappears again on neutralising the excess of acid.—S. H.

*Substitution of the Amido Group by Chlorine, Bromine, and Cyanogen in Aromatic Compounds.* T. Sandmeyer. Berichte, 17, 2650.

THESE substitution products are obtained by the action of the cuprous compounds of the halogens on the diazo-derivatives. To prepare metachlornitrobenzene from metanitraniline, 4 grm. of the latter are dissolved in 7 grm. hydrochloric acid (s.p. gr. 1.17), 100 grm. water, and 20 grm. of ten per cent. cuprous chloride solution added, and the whole heated almost to boiling. From a separating funnel, 25 grm. of sodium nitrite in 20 grm. of water are added, drop by drop. A heavy oil collects at the bottom of the vessel, nitrogen being evolved, and the oil, on cooling, solidifies. A yield of 4 grm. metachlornitrobenzene was obtained of m.p. 45°. By acting upon paratoluidine in a similar manner, and distilling the product of the reaction with steam, parachlorotoluene was formed, boiling at 156° to 157°. On adding cuprous chloride to a saturated solution of the hydrochloride of paratoluidine, the author observed the formation of a crystalline double salt, which dissolved on warming. Orthotoluidine, by the same treatment with cuprous chloride, yielded orthochlorotoluene. In this case the yield is small, orthoacetol being the chief product. Orthoamidophenol gave orthochlorophenol. From paraphenylenediamine, paradichlorobenzene was prepared; and from metaphenylenediamine the corresponding dichlorobenzene. To obtain bromobenzene from aniline, in place of cuprous chloride, a mixture of crystallised

copper sulphate, potassium bromide, sulphuric acid, and copper turnings were employed, and heated until nearly colourless; the aniline added, again heated, and sodium nitrite solution dropped in. In substituting the amido by the cyanogen group, a solution of the cyanide of copper is first prepared by adding potassium cyanide to copper sulphate solution, heating until the first precipitate is redissolved. A solution of diazobenzenechloride is now added slowly, and the mixture distilled; the oily distillate extracted with ether, washed with caustic soda and dilute sulphuric acid and fractionated.—J. B. C.

*Improvements in the Preparation of Halogen Derivatives of Tetramethyldiamidobenzophenone and Analogous Ketone Bases.* John Henry Johnson. A Communication from Heinrich Caro, chemist to the Badische-Anilin und Soda-Fabrik, Ludwigshafen-on-the-Rhine, Germany. Eng. Pat. 4550, March 13, 1884.

THE ketone bases are treated with trichloride or oxychloride of phosphorus, or the corresponding bromine compounds, when the oxygen of the carbonyl group becomes replaced by Cl or Br. The halogen derivatives thus obtained are unstable blue colours, which readily undergo condensation in the presence of amines, giving rise to triphenyl-methane derivatives, or allied bodies. The following is given as a typical illustration of the process:—Dry powdered tetramethyldiamidobenzophenone is mixed with 1½ times its weight of phosphorus trichloride at the ordinary temperature. The replacement of the oxygen by chlorine is indicated by a spontaneous rise of temperature, and by the mixture becoming blue. During the early stage of the reaction the temperature is not allowed to rise above 40° to 50°C., but after several hours heat may be applied in a water bath to complete the reaction. It is not necessary to actually isolate these unstable blue chlorine substitution products, but the reaction can be performed in the presence of another amine, so as to produce the desired phenyl-methane derivative.—R. M.

*The Production of Violet and Blue Colouring Matters of the Rosaniline Series by Treating Aromatic Amines with Alkylated Amido-Derivatives of Benzoyl Chloride and of Benzophenone.* Charles Denton Abel. A Communication from the Farbwerke, vorm. Meister, Lucius and Brünig, Höchst-on-the-Maine, Germany. Eng. Pat. 4961, March 15, 1884.

THE inventors give as an illustration of the process claimed the following series of reactions:—Dimethylamidobenzoyl chloride (Miehler, Ber. ix. 401) is by means of PCl<sub>5</sub> converted into dimethylamidobenzoylchloride—

and the latter mixed with an excess of diethylaniline and aluminium chloride and gently heated when a mixed ketone is first formed, having the formula—

This ketone (Miehler, Ber. ix. 716), in the presence of aluminium chloride, condenses with a second molecule of diethylaniline, producing dimethyltetraethyltriamido-triphenylmethane:—

(See also O. Fischer, Ber. xii. 1690.) The latter is a blue violet colouring matter, and a very blue shade is obtained by employing methylphenylamine instead of diethylaniline. The alkylated amidobenzophenones described can be isolated and condensed with other tertiary aromatic amines by means of aluminium chloride, carbonyl chloride, phosphorus trichloride and pentachloride, anhydrous ferrie chloride, zinc chloride,

etc. In the presence of sulphuric acid, condensation occurs with secondary amines. Thus the above ketone, with methyl-diphenylamine, yields a very blue violet colouring matter of the formula—

It is of course necessary to isolate the ketones, unless the colouring matter is to contain different radicals. A list of the secondary and tertiary amines, ketones, etc., employed in the syntheses is given in the specification.

—R. M.

*Improvements in the Manufacture of Colouring Matters of the Rosaniline and Pararosaniline Series.* Frank Wirth. A Communication from Emil Erlenmeyer, Frankfort-on-the-Maine, Germany. Eng. Pat. 5021, March 17, 1884.

ACCORDING to this invention, red, violet, and blue colouring matters of the rosaniline series are produced by oxidising mixtures of methylated amines with primary, secondary and tertiary aromatic amines. Various mixtures of methyl-violet and aniline, or "mineral green," aniline and arsenic acid are also given. The same materials in different proportions can also be oxidised by means of nitro-benzene in the presence of iron filings. The next section of the patent gives processes for the preparation of violet and blue colouring matters by the oxidation of combinations of methylated amines with secondary and tertiary aromatic amines. Thus, for the preparation of colours from dimethylaniline and diphenylamine, the two bases are gently heated with acetic acid, cupric sulphate and common salt for twenty-four hours to 60° to 80° C. with free access of air. Other variations in the process are given, such as the use of a methyl-violet and diphenylamine or benzyl, methyl or ethyldiphenylamine, etc. By heating a mixture of 170 parts diphenylamine, 140 parts methylphenylnitrosamine and 150 parts zinc chloride, or 107 parts monomethylaniline or 60 parts dimethylaniline, 200 parts diphenylnitrosamine and 150 parts zinc chloride to 100° C. for about twelve hours, a blue colouring matter is produced.—R. M.

*Improvements in the Manufacture of Violet Colouring Matters.* Herbert J. Hadden. Communicated by Dr. Hugo Hassenkamp and the Farbenfabriken vorm. F. Bayer & Co., Elberfeld, Prussia. Eng. Pat. 7645, May 13, 1884.

THE object of this invention is to obtain an economical production of sulphonated benzyl violets. Instead of sulphonating the colouring matter directly as heretofore, the leuco-base is acted upon, the ordinary methyl-violet being first reduced and then benzylated; or the benzylated violet is reduced and then sulphonated; the sulpho-acid of the leuco-base being converted into colour by oxidation. The reduction of the violets to the corresponding leuco-bases is effected by means of zinc dust in acetic acid solution, or by any other method; and the leuco-base is benzylated by treating in a closed vessel with benzyl chloride and sodium hydroxide. The benzylated leuco-bases are sulphonated by hot sulphuric acid of 66° B $\epsilon$ , or by cold fuming acid, mono-, di-, or trisulphonic acids being produced according to the number of benzyl groups present. The products are sent into the market as calcium or sodium salts.

—R. M.

## V.—TEXTILES: COTTON, WOOL, SILK, Etc.

*Treating Cotton and Woollen Rags and Fibres.* John Illingworth. Amended Specification. Eng. Pat. 2796, June 5, 1883.

THE inventor claims the use of a rotary cage, working within a heated flue or boiler, for the purpose of drying fibrous materials that have been previously soaked in

dilute sulphuric acid, the object being to disintegrate the vegetable portion. After drying, the speed of the rotary cage is increased, thus causing it to act as a willow. When thoroughly dusted, an alkaline mixture of soda, chalk, or lime is introduced for the purpose of neutralising the acid remaining in the fibre, after which it is again dried. The drying is assisted by means of an exhaust fan.—E. J. B.

*Waterproofing Textile and other Fabrics.* John Smith Sweet. Eng. Pat. 133, January 1, 1884.

THE fabrics are saturated with a composition consisting of linseed oil, soft soap, patent dryers, olive oil, and oil of caraway. They are then exposed to the air or in heated rooms, and finally calendered.—E. J. B.

*An Improved Method of and Apparatus for Treating Fibres, Rags, and Woollen Fabrics.* John Illingworth. Eng. Pat. 493, January 3, 1884.

THE object of this invention is to destroy the vegetable portion of mixed rags or fabrics. This is done by means of hot hydrochloric acid gas dried by passing through sulphuric acid. Instead of sulphuric acid, sulphate of chalcium (*sic*) may be employed. When the action is completed, a fine spray of ammonia solution is introduced for the purpose of neutralising any remaining acid. The operations are conducted in a revolving cage furnished with spikes for the purpose of thoroughly stirring the material. The specification is accompanied by elaborate drawings of the apparatus employed.—E. J. B.

*Improvements in the Treatment of Fibrous Materials for the Preservation thereof.* Heinrich Wilhelm Kuemeyer. Eng. Pat. 3790, February 22, 1884.

THE improvements consist in coating yarn or fabric with basic copper or zinc carbonate by alternately soaking in a solution of copper or zinc sulphate and carbonate of soda. The method has this advantage over the old methods of impregnation with copper sulphate or copper or zinc soaps—viz., that the preservative is not so readily removed.—E. J. B.

*Improvements in the Treatment of Vegetable Fibres, and of Yarns and Fabrics Manufactured therefrom.* Dr. August Prinz and Emil Quellmalz. Eng. Pat. 5338, April 2, 1884.

THIS invention relates to the treatment of such fibrous substances as nettle fibre, reed, hemp, flax, and particularly jute. The process consists in macerating the fibre in a cold dilute solution of chloride of lime for 20 to 50 hours. It is then heated under pressure with an alkaline lye containing a proportion of benzene, naphtha, or bisulphide of carbon. The inventors claim that by this process such fibres as the above mentioned can be entirely freed from extraneous substances, and can be rendered fit for weaving into the finest fabrics.

—E. J. B.

*Improvements in the Manufacture of Waterproof or Impermeable Fabrics.* Sydney Pitt. Communicated by the Company for Manufacturing Waterproof Fabrics, St. Petersburg. Eng. Pat. 10,600, July 25, 1884.

THE fabric is first washed in a weak solution of soda, then with water, and afterwards dried. It is then immersed in sulphuric acid of from 54° to 56° Beaumé for 40 to 80 seconds, after which it is rinsed in cold water and placed in a bath of weak ammonia for eight hours. After this preliminary treatment the fabric whilst still wet is soaked in the following solution:—

	526 parts Colophony
	180 " Soda crystals
3000 to 4000 parts of water	90 " Green soap
	195 " Silicate of potash
	9 " Caustic potash

After remaining in this solution for three hours it is placed for an hour in a bath containing five per cent. of

sulphate of alumina, after which it is rinsed and dried. Finally, the fabric is subjected to the action of rotating brushes covered with a mixture of paraffin, wax, and colophony. With the exception of the sulphuric acid treatment, the above process can be applied to woollen goods.—E. J. B.

*The Disintegration of Vegetable Tissues.* John Adams Southmayd. Complete Specification. Eng. Pat. 11,877, September 2, 1884.

This invention consists in a method of reducing vegetable substances to the state of pulp by first boiling with an alkaline lye and then suddenly ejecting the mass under the existing steam pressure of 75lb. to 150lb. The inventor claims a considerable saving of chemicals. By first washing with water, and then introducing a solution of chlorine in water, the pulp may be bleached in the boiler. The mass of white pulp may then be ejected as above. The boiler, which is of a peculiar construction, is conical in shape. A drawing accompanies the specification.—E. J. B.

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

*On the Action of Bisulphites upon Chlorates.* Dingl. Polyt. Journ. 1884, 254, 226.

SOME observations on the reducing action of sulphurous acid and its acid salts are published by M. Prud'homme in the Bulletin de Mulhouse, 1884, p. 436. Free sulphurous acid yields with chloric acid, sulphuric and hydrochloric acids, whilst the alkaline bisulphites reduce chlorates only partially, as represented in the following equations:  $\text{NaClO}_3 + \text{NaHSO}_3 = \text{HClO}_2 + \text{Na}_2\text{SO}_4$  and  $\text{NaClO}_3 + 2\text{NaHSO}_3 = \text{HClO} + \text{Na}_2\text{SO}_4 + \text{NaHSO}_4$ . The sodium bisulphite formed in the latter reaction may again act upon the bisulphite and set sulphurous acid free, which in its turn will exert a reducing action. By pouring a 30° sodium bisulphite solution into a concentrated solution of sodium chlorate (about 100 grammes to the litre) a violent reaction takes place, especially when the chlorate solution is warm. A strong odour of chlorine oxidation products and sulphurous acid is developed while the reaction is going on. The solution decolourises indigo and other colouring matters, and converts cellulose into oxycellulose, which can readily be recognised by its affinity for methylene blue, etc. When mixed with aniline salts it forms aniline black, proving the correctness of Rosenstiehl's theory of the formation of aniline black by various oxidation products of chlorine. When chlorates and bisulphites act upon each other in the presence of alcohol, among other products chlorinated ethers are formed.—F. M.

*Aniline Black.* L. Liechti and W. Suida. Dingl. Polyt. Journ. 254 [6], 265, 1884.

TAKING advantage of the inter-molecular change which chlorate of aniline suffers when exposed to the atmosphere in the crystalline state, the authors have prepared aniline black without the aid of a metallic salt. The aniline chlorate was prepared by adding moist, recently precipitated aniline sulphate to a saturated solution of barium chlorate, and after some time decanting the clear neutral solution from precipitated barium sulphate. The solution of chlorate of aniline yields after a time, colourless prisms of that salt, which by contact with atmospheric air are directly converted into aniline black ("Emeraldine"). The application of heat causes the change to be of an explosive nature. No alteration of crystalline form takes place, the crystals of aniline chlorate simply become bluish black. The authors have studied the behaviour of the pure aniline chlorate solution under varying circumstances, and find: (1) That it can be boiled without change; (2) that the addition of hydrochloric acid with subsequent heating brings about a copious formation of emeraldine; (3) that dilute sulphuric acid causes the precipitation of very

little emeraldine; (4) ferric chloride and (5) vanadium chloride act like hydrochloric acid; (6) the solution warmed with cupric sulphate, simply becomes brown; (7) tartaric and acetic acids are without action; (8) warming with dilute nitric acid effects little alteration of the solution, but on the subsequent addition of ferric chloride there is thrown down a precipitate of blue passing to green colour; (9) dilute chromic acid mixture brings about a copious formation of black; (10) the solution boiled with ammonium chloride remains unaltered but subsequent addition of cupric sulphate causes a black precipitation; (11) boiled with ammonium vanadate, the solution does not yield emeraldine; (12) hydrochloric acid in the cold causes the precipitation of emeraldine from a brown solution, which if warmed becomes reddish violet and yields more emeraldine. The crystals of aniline black yield, after treatment with hydrochloric acid, alcohol, ether and dilute potash solution, pure emeraldine corresponding in its properties with the aniline black described by Nietzki and giving on analysis, numbers which lead to the formula  $\text{C}_{18}\text{H}_{15}\text{N}_3\text{HCl}$ . The authors found the more abundant products of the distillation of emeraldine with zinc dust to be diphenylphenylenediamine, diphenylamine, diaminodiphenylamine, the less abundant, phenylenediamine, aniline and ammonia. The correctness of Nietzki's view that the black is to be regarded as a hydrochloride of the base  $\text{C}_{18}\text{H}_{15}\text{N}_3$  does not receive confirmation at the authors' hands. They have found that chlorine is present in all the salts derived from emeraldine and that this chlorine cannot be eliminated by the action of oxide of silver. They therefore incline to the view that emeraldine is a chloro-substitution product of the base  $\text{C}_{18}\text{H}_{15}\text{N}_3$ . The correctness of this view derives confirmation from the facts that the chlorates of the heavy metals yield oxides of chlorine when decomposed, and of such,  $\text{Cl}_2\text{O}_2$  for example is capable of forming chlorinated derivatives of organic bodies. To obtain some explanation as to the formation of aniline black upon the fibre and the part played in the reaction by the usually added metallic compounds the authors made the following experiments. Dissolved aniline chlorate was mixed with dissolved aniline hydrochloride in molecular proportions respectively of 1:0, 1:1, and 1:2. The fabric was padded in these solutions, experiments being made at the same time with similar solutions containing a trace of vanadium chloride. On hanging at from 31° to 35° the fabric containing vanadium rapidly blackened, that free from vanadium underwent no change. On treating the latter with dilute hydrochloric acid, a formation of emeraldine soon took place. Also on heating the vanadium free fabric to about 80° to 90°, a formation of black took place even upon the portions not heated. It would thus appear that for the formation of the black upon the fibre, the chloric acid must be in a liberated condition. The metals employed in the production of aniline black are, according to Rosenstiehl, those the chlorates of which are easily decomposed at comparatively low temperatures; hence it has been considered that these simply act by supplying lower oxides of chlorine. Liechti and Suida consider that the presence of free hydrochloric acid is essential to the reaction. If a colour containing aniline hydrochloride, potassium chlorate and cupric chloride be taken, the two latter bodies are mutually decomposed. The chlorate of copper reacts with the aniline salt as may be expressed by the equation:

The hydrochloric acid thus set free, is able in the presence of potassium chlorate to continue the oxidation which the salt of vanadium or copper started, thus:

A small amount of copper or vanadium is therefore able to bring about the formation of a comparatively large quantity of the black. From equation II, it would appear that a portion of the aniline employed might be

combined with a feeble acid, in order to decrease to some extent the tendering action of the hydrochloric acid upon the fibre.—W. D. B.

*Iron Mordants in Silk Dyeing.* Dingl. Polyt. Journ. 254, 437.

THE iron (ferrie or "red") mordants used in silk dyeing are prepared by oxidising ferrous sulphate by means of nitric acid. The product is usually a basic ferrie sulphate containing a certain small proportion of ferrous salt, and sometimes some nitric acid. The influence of these occasional constituents has been investigated by L. Liechti and W. Suida (Mitt. Techn. Gew., Wien, 1884, 55). These authors prepared mordants of the following typical composition respectively:—(1)  $\text{Fe}_2(\text{SO}_4)_3 \cdot 0.11$  of 30° B.; (2)  $\text{Fe}_2(\text{SO}_4)_3 \cdot \text{NO}_3 \cdot 0.11$  of 30.5° B.; and (3)  $\text{Fe}_2(\text{SO}_4)_3 \cdot (\text{OH})_2$  of 31° B. Weighed quantities of silk were allowed to lie in these solutions under the usual conditions, and after further treatment by the ordinary method the quantity of iron fixed in the fibre was determined. The most favourable result obtained was with (3), 12 per cent. of  $\text{Fe}_2\text{O}_3$  being fixed, whereas from (1) only 8 per cent. was taken up by the silk. The weight from (2) was 11 per cent., a result very little inferior to that obtained with (3), notwithstanding that the latter was the more basic. Most of the commercial products examined by the authors approximated in composition to (1), but contained also a small but varying proportion of nitric acid. One of the standard products used at Crefeld had the following composition:—Total iron=11.5 per cent., as ferrous salt 0.5 per cent., sulphuric acid ( $\text{SO}_4$ )=27.2 per cent., corresponding to the formula  $\text{Fe}_2(\text{SO}_4)_3$ . With respect to the influence of ferrous salt upon the dissociation phenomena of the mordant the authors find that in regard to the dissociation produced by water alone it is considerably less in presence of ferrous salt, whereas, strange to say, the dissociation caused by the silk fibre is not in any way affected. The question therefore of the employment of mordants containing residual ferrous salt is still an open one.—C. F. C.

*Potassio-Antimony Oxalate as Tartar Emetic Substitute.* Dingl. Polyt. Journ. 255 [3], 122.

FOR fibres of vegetable origin tannin has always been employed as the most efficacious mordant for artificial colouring matters. As a type of the kind of mixings to be employed as a means of conveying aniline colouring matters on to cotton fabrics we have always had a suitably thickened mixture of colouring matter (salt of rosaniline or substituted rosaniline) with tannic acid and acetic acid added to avoid premature precipitation. Such lakes were, however, soon found to be of very limited fastness, to lose considerable quantities of colour not only on soaping, but even on mere washing and steaming. The consequence was loss, and what was still worse, degradation of the whites and of the colours printed along with the above. It was impossible—*g.*, to employ an alizarine steam red together with methylene blue fixed only with tannin. The idea developed then to fix the tannin not only by a colouring matter, but also by a metallic oxide, and Thomas Brooks, of Manchester, made the proposal to accomplish this end by means of antimony, and to apply the same as tartar emetic. This salt was chosen on account of being dissolved by water *in toto*—*i.e.*, without the formation of insoluble compounds, and also because whilst fixing the tannates it exercises no further and degrading action on the other colours. The Société Industrielle de Mulhouse in 1881 awarded a medal to Mr. Thos. Brooks for his successful improvement. An objection was the cost, the said salt being one of the dearest antimonial preparations. Moreover, tartar-emicetic cannot be replaced by such antimony salt as the trichloride since the same yields with water an insoluble basic salt and free acid. Of the attempts made to substitute cheaper metallic salts for tartar-emicetic, H. Schmidt's proposal to employ acetate of zinc met with a certain amount of success in practice (Chemiker Zeitung, 1881, p. 949). Acetate of zinc acts well when it is simply the intention to fix the tannin,

and is employed in several print works. In the case of more complicated patterns, such as when it is desired to fix aniline colours along with alizarin red, antimony takes the first place, and the introduction into commerce of the cheaper oxalate instead of the tartarate was a step in the right direction. The double oxalate had indeed been known for some time, but was sold at a price out of proportion to its contents in antimony. Tartar emetic contains 43.7 per cent. of  $\text{Sb}_2\text{O}_3$ , and  $\text{Sb}_2(\text{C}_2\text{O}_4)_3 \cdot 6(\text{H}_2\text{O})$  only 23.67 per cent.  $\text{Sb}_2\text{O}_3$ . Hence in making up an antimonial bath we require double the quantity of the latter salt. At the present time the salt in question is sold at a price proportionate to its percentage of Sb, and to the price of the organic acid contained in the salt. If solutions of the double oxalate be much diluted a slight deposit of insoluble basic salts is observed, but does not appear to cause any disturbance. This property is indeed of use in making printing trials on the small scale. Thorough washing is essential in order to remove any basic salt which might attract fatty acids during the soaping process, and then degrade the whites by means of waste colouring matter.—H. A. R.

*Phenylhydrazine as a Discharge on Bistre.* Dingl. Polyt. Journ. 255 [3], p. 128.

G. SCHAEFFER, in *Bulletin de Mulhouse*, 1884, p. 57, states that phenylhydrazine, owing to its reducing properties, may be employed in a similar manner to hydroxylamine (see *Bull. de Mulhouse*, 1883, 250, p. 380) to produce white patterns on a ground of manganese or bistre brown.—H. A. R.

*Improvements Applicable to the Dyeing of Black Colours upon Cotton and other Vegetable Fibres.* Joseph Knowles Kaye. Eng. Pat. 2372, January 30, 1884.

THE material is dyed in a bath containing logwood extract, tannic acid, and carbonate of copper. It is removed from the bath, allowed to stand for a few hours, and then saddened by immersion in a cold weak solution of iron liquor. Such a method gives a finer and more durable black than has hitherto been obtained.—E. J. B.

*Improvements in Dyeing Wool or other Similar Animal Fibre, and in Apparatus Employed therein.* Charles Holliday and Ernest William Hirst. Eng. Pat. 2837, February 6, 1884.

THE improvement consists in dyeing wool in a chamber of special construction. The dyeing or mordanting solution enters at the bottom of the chamber, and flowing upwards by a central tube is distributed evenly over the material to be dyed, which is placed on a series of perforated plates. The chamber is connected with an air-pump, and is furnished with a steam coil for heating. The inventors claim:—"The method and combination or arrangement of apparatus for dyeing wool and other similar animal fibre, whereby the air or vapour released or generated during the operation is enabled to pass off without passing through the fibres, in order to prevent deleterious effects upon the fibres from ebullition or disturbance thereof, and to obtain better distribution of liquid passing there through." By using such an apparatus a considerable economy of dye is effected, particularly in the case of indigo.—E. J. B.

*Manufacture of Mordants and Colouring Matters from Glucosides, Tannin and Bitter Principles.* W. L. Wise. A Communication from C. H. Knoop. Eng. Pat. 4480, March 6, 1884.

THIS relates to the production, by the action of oxidising agents, of colouring matters which are soluble in water and precipitated by alkalis, and of which the less highly oxidised may be used as mordants, while the more oxidised give fast colours without the use of separate mordants on spun and woven fabrics, either animal or vegetable. As an example, 20 kilos. of extract of Brazilwood are dissolved in boiling water, to which is added a little nitric or hydrochloric to precipitate the

resin, and the clear brazilin solution is removed, and a solution of 5 kilos. of permanganate of potash is mixed with it with constant agitation. The resulting precipitate is filtered off, washed and dissolved in nitric, hydrochloric, sulphuric, or oxalic acids, and if necessary boiled. After cooling, it is neutralised with ammonium carbonate, and forms a reddish-violet colouring matter in the form of a paste. Many other chemicals may be substituted for permanganate of potash, with varying results. Tetrachloride of tin, chlorate and chromate of potash, and salts of mercury, chromium arsenic, manganese, etc., and frangulin, machurin, quercitrin, carthamin, homatin and catechin are spoken of as suitable materials.

—H. R. P.

*Improvements in Bleaching Fibrous Materials, Fabrics and Paper-pulp of Vegetable Origin.* Robert and Alexander Watson Townsend, of Port Dundas, Glasgow, manufacturing chemists. Eng. Pat. 12,732, September 24, 1884.

THE object of this invention is to shorten the time required, obtain improved results as regards whitening action, and avoid injury to the materials operated on when bleaching fibrous material, fabrics or paper-pulp, of vegetable origin. The invention consists in the employment of one or more of the oxychlorides of magnesium, barium, strontium, potassium or sodium. For bleaching jute, esparto, wood-pulp, cane-pulp or other vegetable material, the inventors propose to employ oxychloride of magnesium in solution, and of the strength of about 11° T., and claim that one gallon of the said solution will bleach about five pounds of the materials when these are in the condition in which they are ordinarily subjected to a bleaching process. "The bleaching action will in most cases take place on steeping the materials in the solution at the ordinary temperature for a suitable length of time, but the action may be increased or hastened by raising the temperature." No acid is added to the solution, nor do the materials require to be "sour" or treated with dilute acid. The "improved process effectively, and without injuring the fibre, bleaches jute and other vegetable materials of kinds which cannot be satisfactorily treated by ordinary bleaching without injury to the fibre." The solution is prepared either by dissolving the salt previously prepared in any known way, or else by the double decomposition of bleaching powder solution and the solution of the sulphate of magnesia, or the sulphate of one or more of the bases hereinbefore named.

—H. A. R.

## VII.—ACIDS, ALKALIS, AND SALTS.

*On the Oxides of Nitrogen.* Prof. W. Ramsay and J. Tndor Candall. Proc. Chem. Soc. [3], 22-23.

IN this research it is shown—

1. That the green or blue liquid obtained by the action of arsenious anhydride on nitric acid consists of a mixture of nitrous anhydride and nitric peroxide, in proportions depending on the strength of the nitric acid and the temperature at which the volatile liquid is condensed.

2. That if a dehydrating agent, such as sulphuric acid, be present in sufficient quantity the distillate consists of pure peroxide, and that this process is by far the most convenient one for the preparation of the peroxide.

3. That if oxygen be passed over the blue liquid, the vapours condensed in a freezing mixture are still blue or green; a great excess of oxygen is necessary to effect conversion from nitrous anhydride into peroxide.

4. That when excess of nitric oxide is passed along with the peroxide into a cooled bulb, the trioxide is produced, the amount of trioxide depending on the temperature of the condenser.

5. The vapour-density of a liquid of a deep-blue colour, containing about 30 per cent. of trioxide and 70 per cent. of peroxide, shows that the trioxide cannot exist in the gaseous state, but at once dissociates into nitric oxide and peroxide on changing to gas. The theo-

retical vapour-density of such a mixture was calculated from a formula deduced from the second law of thermodynamics by I. Willard Gibbs, which shows the relations between temperature, pressure, and vapour-density of the mixture of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$  in the gaseous peroxide; and it was found that the vapour-densities of a mixture of  $(\text{NO}_2 + \text{N}_2\text{O}_4)$ , (partly present in the original liquid as peroxide, partly formed by the decomposition of the  $\text{N}_2\text{O}_4$  present into  $\text{NO}$  and  $(\text{NO}_2 + \text{N}_2\text{O}_4)$ ), with the  $\text{NO}$  produced by the decomposition of the  $\text{N}_2\text{O}_4$ , calculated by means of Gibbs' formula, are identical, within limits of experimental error, with those obtained by direct experiment.

6. The presence or absence of moisture does not appear to affect the reaction between  $\text{NO}$  and  $\text{O}_2$ .

7. It is probable that  $\text{N}_2\text{O}_3$  undergoes dissociation with rise of temperature, even while liquid.—W. S.

*New Apparatus for the Production of Ammonia Soda.* Dingt. Polyt. Journ. 254 (12), p. 488.

THE Société Anonyme des Produits Chimiques de l'Est, following the patent of D. Maguin, of Nancy (D.R.P., Kl. 75, No. 28,761, of December 11, 1883), seek to obtain a more complete action of the carbonic acid on the ammoniacal liquors by causing the latter to flow uninterruptedly from a reservoir R (Fig. 1), through a pipe *t*, to fill the series of vessels B, C, etc. to a certain height, the liquor passing from one vessel to the next through the overflow pipes *b, c, d*, etc., and being at last run off from the last vessel G by opening the cock *h*. At the same time, brine flows into the vessel A from the washing apparatus *w*, which is fed from S, and this absorbs the ammonia from the gases before their escape from the apparatus. This brine mixes in the vessel B with the ammoniacal liquor, and its flow is regulated so as to always form an appropriate percentage of the ammonia contained in the mixture. The carbonic acid is let in with a certain velocity, and, traversing the vessels in a direction opposite to that of the ammoniacal liquor, passes through the washing apparatus *w*, and escapes through the pipe *v* into the air. Whilst the pure carbonic acid is introduced by the pipe *k*, the impure carbonic acid enters through the pipe *l*, so that the latter first mixes with the pure gas after this has passed from F into the next vessel E. In every vessel, the gas first passes through an inverted funnel, the larger circumference of which is serrated, and rises up through the liquor, which it dashes about in the upper part filled with gas, and then passes over into the next vessel in the series. For the recovery of the ammonia after the separation of the precipitated sodium bicarbonate, the whole of the free ammonia and carbonic acid is driven off in the vessels A to C (Fig. 2), and the decomposition of the ammonium chloride, by means of lime, is effected in the vessels D and E. While the apparatus is working, the clear liquor flows uninterruptedly through the pipe *t* into the collecting vessel M, then through an overflow pipe *a* to the distilling vessel A, and likewise through *b* and *c* into the stills B and C. The liquid coming over from this last vessel C into the vessel D contains no more carbonate of ammonia, but only ammonium chloride. Milk of lime is therefore constantly pumped into the vessel D through the pipe *s*, and reacts upon the liquor likewise continually flowing in, and sets free ammonia. As soon as the liquor in the vessel D has reached a certain height, a portion is allowed to flow over into E by opening the cock *h*. Both vessels D and E are provided with inverted troughs with toothed edges, in order to favour the disengagement of the ammonia. The steam entering by the pipe *r* at the bottom of E, drives out the last traces of ammonia still in the liquid, and the steam with the ammonia flow through the pipe *e* into the vessel D, where, after becoming considerably enriched with ammonia in passing through the liquor, it then enters by the pipe *f* into the inner funnel *x* of the vessel C, until finally it arrives along with ammonia and carbonic acid by the pipe *z* in the collecting vessel M, and further into the pipes *m*, which are cooled in a trough containing water. The steam becomes for the greater part condensed here, and flows

back in the somewhat inclined pipes *m*, into the collecting vessel, from which it reaches the apparatus again through the overflow pipe *a*. The mixture of ammonia

into the form of sulphide of calcium; and this, at a high temperature in the presence of steam, yields sulphuretted hydrogen and lime. The chief object in using sawdust

and carbonic acid gases, with only a small quantity of water vapour, flows over through the pipe *h* into the vessels *O* and *P*, by the liquor in which it becomes absorbed.—G. H. B.

*Process for the Recovery of Sulphur from Soda Waste.*  
Dingl. Polyt. Journ. 255, 206, 1885.

II. GROUVEN (Ger. Pat. 29,848, May 30, 1884) mixes alkali waste with 10 per cent. of sawdust, and from 10 to 25 per cent. of water, according as the waste is new or old, in a kneading machine, and then moulds the resulting doughy mass into tubes, in an ordinary press. The most suitable length for these tubes is 250mm., the external diameter being 45mm., and the internal 20mm. The tubes are exposed to the action of the air, under cover, for about two days, when they become hard and brittle. They are next heated in retorts, along with steam. The carbonic oxide and hydrogen generated throughout the mass, completely reduce all the oxides of sulphur contained in the waste. Almost all the sulphur is converted

is to give great porosity to the moulded cylinders, this being essential to the complete decomposition of the mass. When the proper temperature has been maintained, practically, all the sulphur is removed in three hours; and the residue left in the retorts is yellow coloured, and on boiling with dilute hydrochloric acid, neither carbonic acid, nor sulphuretted hydrogen, nor sulphurous acid, is evolved. On fusing with nitrate of potash, only from one to two per cent. of sulphuric acid is obtained, and this existed principally as sulphate of lime. This residue contains from 85 to 90 per cent. of quicklime, and can be used for mortar making.—W. M.

*Lepid's Process for Preparation of Barium and Strontium Hydrates.* Dingl. Polyt. Journ. 254, 436.

THIS process (Ger. Pat. 28,757, 1883), consists essentially in treating the carbonates with steam superheated to a temperature higher than the melting point of the hydrates. The details are as follows:—The carbonate is

introduced into the iron pots E (Fig. 1), which, having been brought to a low red heat, are successively removed, and their contents transferred to the retort A. Superheated steam is then introduced into A, through *d*: the carbonate is decomposed, and the molten hydrate flows by way of *n* into B. *t* is a tube containing barium or strontium hydrate, by the melting of which the attainment of the requisite temperature, by the steam

this pipe, and solidifies as it strikes against the bottom of the cylinder; while the gaseous carbonic acid, and any air which has been carried over escape by the pipe *o*, the openings of which, at *t* and *u*, are covered with fine wire gauze. The top G is taken off when it is desired to remove the solid carbonic acid. This apparatus is said to produce a much larger quantity than Thilorier's system.—W. M.

Fig. 1.

issuing through *d*, is ascertained. The molten hydrate is run off from B, through *s*, into iron moulds. A supplementary patent (29,153, 1884), contains modifications and improvements in detail. It is found that the carbonates are best prepared by working them into a paste with 30 to 40 per cent. of a weak caustic lye—the presence of the alkaline hydrate facilitates the separation of the molten earth-hydrate from the undecomposed carbonate—which is then made into balls or hollow cylinders, which require to be suddenly heated to a high temperature in order that they may not fall to pieces with the loss of water.—C. F. C.

*Apparatus for the Preparation of Solid Carbonic Acid.*  
Dingl. Polyt. Journ. 255, 201, 1885.

For the solidification of carbonic acid, Dueretet (*Comptes Rendus*, 99, 235, 1884) employs an ebonite cylinder R, the

cover of which can be fixed by the clamps S. The pipe T passes through the cover and reaches almost to the bottom of the vessel. The liquid carbonic acid enters by

*Preparation of Sulphuric Acid from Gypsum.* Dingl. Polyt. Journ. 255 [2], 87.

By heating a mixture of two parts of calcium sulphate with one of ferric oxide, to a bright red heat, *Scheurer-Kestner* obtains all the sulphur as sulphuric anhydride. Towards the end of the process, sulphurous acid and oxygen are formed, but this decomposition is considerably retarded by adding either calcium fluoride or chloride to the mixture. A similar reaction takes place at a lower temperature with the sulphates of other bibasic metals, such as lead or magnesium.—S. R.

*Improvements in the Method of and Apparatus for Manufacturing Sulphuric Acid.* M. Finch, W. J. & S. Willoughby, Plymouth. Eng. Pat. 3086, February 11, 1884.

THE sulphurous and nitrous gases from the pyrites or sulphur burners, after passing through a Glover tower, are conducted into a pump, or any other contrivance suitable for drawing and forcing the same. Before entering the barrel C (Fig. 1) of the pump, they are made to pass

through the enlargement B, where they are subjected to the action of a spray of steam, water or acid, until they become saturated. They are then forced through the pipe D into a tank or tower G (Fig. 2), wherein they are compressed to promote the oxidation of the sulphurous gas. Sulphuric acid is formed, which falls to the bottom, whence it is drawn off by a valve O. The tower is provided at the top with a valve P, so constructed, that when the gases attain a certain pressure, the uncondensed

portion thereof may escape through the same, and pass into another tower of similar construction; and this is repeated until the desired conversion into sulphuric acid

has been effected. From the last tower, the gases, deprived of sulphurous acid, escape into a Gay-Lussac column for the absorption of nitrous gases.—S. H.

*Improvements in the Manufacture of Soda and Chlorine.*  
Charles Wigg, Liverpool, and John Waller Pratt, Runcorn. Eng. Pat. 3673, February 21, 1884.

THE object of this invention is to treat the residual ammonium chloride liquors of the ammonia soda process in such a manner as to obtain, not only all ammonia, but also all the chlorine, in a condition suitable for the manufacture of more soda, and of bleaching powder. For this purpose the ammonium chloride solution is boiled in a closed boiler, until all the free ammonia and ammonium carbonate which it contains has been volatilised. It is then evaporated, either to complete dryness, or until crystals of ammonium chloride and sodium chloride separate out. The latter can be removed, if found detrimental. The solid ammonium chloride is then mixed with finely ground calcium carbonate, in equivalent proportion. The mixture is transferred to a hemi-spherical pan, heated from beneath, and provided with a tight-fitting, cast-iron hood or dome, resting on its upper rim. On heat being applied, sesquicarbonate of ammonia is volatilised and sublimed to the roof or dome of the pan, to which it adheres. If the dome is maintained at a high temperature, the condensation of the ammonia salt is prevented, and it can be directly passed into brine for the manufacture of soda ash. The residue in the pan consists of a loose, porous mass of calcium chloride, and while it remains hot in the pan, the top of the pan containing the sublimed ammonium carbonate, is removed, and replaced by another tight-fitting cover, provided with an escape pipe, leading to a condenser. Oil of vitriol is then run on to the contents of the pan, whereby hydrochloric acid is produced; whereas, the calcium sulphate, thus formed, is roasted and converted into plaster of Paris. The sublimed ammonium carbonate is dissolved in strong brine, and another molecule of carbonic acid passed into that

solution, causing the formation of sodium bicarbonate, thus:—

The ammonium chloride solution re-enters the cycle of the operations. By using calcium carbonate, the expense for generating and pumping one-half of the total carbonic acid needed for the production of carbonate of soda, is saved. Instead of using calcium carbonate for the decomposition of ammonium chloride, the carbonates of magnesia, baryta and strontia may be also employed. If magnesium carbonate be used, magnesium sulphate—Epsom salts—will be the ultimate product. Barium or strontium carbonate will leave the chlorides of these metals, as residues, in the pan. In place of running oil of vitriol on the chlorides, the latter are dissolved in hot water, filtered and precipitated with sulphuric acid, yielding precipitate of barium or strontium sulphate, and a supernatant solution of hydrochloric acid. The barium sulphate prepared in this way is as “blanc fixe,” an article of considerable commercial value, while strontium sulphate is also suitable for many technical applications.—S. H.

*Improvements in the Manufacture and Storage of Bichromate of Soda.* C. S. Gorman, Ayrshire. Eng. Pat. 4195, March 1, 1884.

250 PARTS chrome iron ore, 150 chloride of sodium, and 250 hydrated lime, are mixed and furnace in presence of superheated steam, at a temperature of 1000° to 1600° F. Hydrochloric acid is evolved and condensed, and chromate of soda is formed, which is dissolved in water, the solution evaporated down and treated with sulphuric acid, to form bichromate of soda. The liquid is then allowed to cool, when sodium chloride and sulphate separate out. The solution of bichromate of soda is further evaporated by hot air, and run in the fluid state into metallic drums, or the evaporation may be carried to dryness.—G. H. B.

*Improvements in the Manufacture of Chromates and Bichromates.* W. J. A. Donald, Glasgow. Eng. Pat. 6731, March 13, 1884.

THIS patent aims at the production of ammonium chromate and bichromate. Chromate of soda, obtained preferably, as described in another patent by the same author, is dissolved and treated with ammonium chloride; sodium chloride is separated by evaporation; and bichromate of ammonia is formed by the addition of a suitable acid, and is obtained in the solid state by evaporation.—G. H. B.

*Improvements in the Evaporation and Concentration of Liquids.* H. E. Newton, London. Communicated by A. Nobel, Paris. Eng. Pat. 5383, March 24, 1884.

THE object of this invention is to provide a rapid method for the evaporation and concentration of liquids. To effect this the liquid is forced in the form of spray into the interior of a tall cylindrical vessel or tower, and at the same time subjected to the action of a current of hot air. The concentrated liquid settles in the lower part of the tower, and can be drawn off at intervals; that portion which is carried over with the air, and the water evaporated, is condensed in suitable vessels. The construction of the apparatus depends in a great measure upon the material operated upon. The illustration shows a form of apparatus suitable for acting upon sulphuric acid. A is a cylindrical tower constructed of lead and lined with a non-corrosive body; it is water-jacketed round the exterior I, and on the bottom II. F is an injector formed by the pipe f' conveying the acid, placed at right angles to the pipe f, which admits a blast of hot air at a suitable pressure; the quantity of acid is of course regulated according to the requirements of the evaporation. E is the pipe for conveying the hot air required for the concentration, the temperature of the air being in this case about 500° C. G is the pipe conveying away the air charged with water and acid vapour, which may be

cooled down to a convenient temperature, and then sent through the leaden chambers; *b* is the pipe which carries off the strong acid after concentration. The lower part of the tower may be advantageously packed with non-corrosive material such as pumice stone, etc. *D* is a pipe which brings the sulphurous acid gas from the pyrites burners on its way to the acid chambers, and thus the heat of this is utilized for the purpose of concentration.

The claims are (1), the concentration of sulphuric acid and other liquids by injecting them into a tower as described, and passing through the spray a current of heated air; (2) the utilisation of the heat of the gases from the pyrites or brimstone kilns, alone or in conjunction with air, for concentrating the spray of sulphuric acid, as described and set forth.—C. C. H.

*Improvements in the Manufacture of Sulphate of Ammonia.* W. A. Meadows, Lancashire. Eng. Pat. 5520, March 27, 1884.

THE absorption of ammonia by dilute sulphuric acid is carried on at a temperature not lower than 100° F. in presence of a small quantity of tar, pitch, oil, fat or like substance, which collects a scum containing the arsenic and iron of the sulphuric acid, and facilitates the removal of these impurities. Pure white crystals of sulphate of ammonia crystallise out.—G. H. B.

*Improvements in the Manufacture of Chlorate of Potash.* J. Wilson, Berwick-on-Tweed. Eng. Pat. 5975, April 5, 1884.

POTASSIUM chloride and magnesia in suitable proportions are mixed with water and run through a series of vessels where saturation with chlorine is effected. Chlorate of potash crystallises out on evaporation of the resulting solution, and the mother-liquor containing magnesium chloride and some chlorate of potash is further evaporated and roasted in a muffle furnace, whereby chlorine, hydrochloric acid and magnesia are obtained.—G. H. B.

*Improvements in Purifying Sulphuric Acid.* W. P. Thompson, Liverpool. Communicated by G. Thomson, Quebec, and W. Kemp, Jarrow-on-Tyne. Eng. Pat. 6215, April 10, 1884.

CHAMBER acid is treated with ammonium sulphide, which precipitates the arsenic and antimony present. The acid is then rendered clear by filtration through finely divided lead, and is further concentrated by evaporation, during which the ammonium sulphate present assists in the expulsion of the last traces of oxides of nitrogen, and a very pure acid is the result.—G. H. B.

*Improvements in Furnaces for the Manufacture of Sulphate of Soda, or Hydrochloric Acid, or for Roasting, or Calcining Ores, or for Analogous Purposes.* W. Black and Thos. Larkin, South Shields. Eng. Pat. 4718, July 16, 1884.

THE substances under treatment are contained in a box-chamber, the cover and bed of which are formed of fire-clay quails or cast-iron plates. This chamber is provided with a mechanical stirrer, the shaft of which is suitably protected from the fire. Fire-places are arranged on opposite sides of the chamber so that the heated gases from them pass both above and below the said chamber, and thence to the main flue. The charge may be introduced by a suitable channel leading from a decomposing furnace or otherwise, while it is removed by specially constructed doors. A flue leading from some convenient part of the chamber allows of the escape of the evolved gases, which thus never come into contact with the products of combustion coming from the fire-places.

—A. R. D.

*Improvements in the Production of Alkali Carbonates, and in Apparatus therefor.* Peter Jensen, London. A Communication from Adolph Vogt and August Figge, Westerhausen, near Magdeburg. Eng. Pat. 13,590, October 14, 1884.

CHLORIDE of potash or soda and finely divided gypsum or sulphate of magnesia are intimately mixed with caustic magnesia, kneaded moist, and dried. The resulting porous mass is broken into pieces and charged into the sulphating furnace, which consists of a series of superposed cast-iron pipes, so set in brickwork that as little as possible of the weight of each pipe falls on the pipe next below. Superheated steam is driven through the charge, which causes the chlorine to pass away as hydrochloric acid, and the sulphuric acid to combine with the potash. The resulting mixture is transferred to another vertical cast-iron retort raised to redness by external heat, and treated with pre-heated carbonic oxide gas, the sulphate being thus reduced to sulphide. When the reduction is complete, the temperature is allowed to fall, and a mixture of carbonic acid and steam passed through the retort. The sulphide is now converted into carbonate, and the sulphur passes away as sulphuretted hydrogen. The resulting mass is lixiviated cold for the extraction of the carbonates. If a mixture of air and steam instead of steam only is driven through the sulphating retorts, chlorine comes off instead of hydrochloric acid. In this case the inner surface of the retort must be protected by a coating of silicious enamel.—A. R. D.

*Improvements in the Process of Manufacturing Permanganates.* Theodor Kemp. Eng. Pat. 8218, October 22, 1884.

THIS is a process for the transformation of manganates into permanganates by an electric current. The negative electrode is placed in water and the positive in a solution of the manganate in question, the two being separated by a porous wall. The electric current causes the permanganate to separate in the cell containing the positive electrode, while the corresponding hydroxide is formed and hydrogen evolved in the other cell.—A. R. D.

*Improvements in and Relating to the Manufacture of Chlorine.* Walter Weldon, Barnstow, Surrey. Eng. Pat. 9305, June 23, 1884.

THIS invention relates to the apparatus employed in the manufacture of chlorine from a chloride of a metal or mixtures of chlorides, by heating them in a current of air, at the same time excluding the products of combustion of fuel. The operation is performed in a regenerative furnace represented in vertical section by Fig. 1; Fig. 2 shows a section across the line CD, and Fig. 3, a section across the line AB. *A*, *A*<sup>1</sup>, *A*<sup>2</sup> and *A*<sup>3</sup> are four vertical brick chambers of a small diameter, but with very thick walls. They communicate with each other at their upper and at their lower extremities, whereas the end

chambers A and A<sup>3</sup> are in direct communication with the regenerators RR. The pipes M and M' serve alternately as outlet pipes for the gas given off in order that the current of air may be reversed at will. The whole furnace is encased by iron plates, and protected as much as possible from loss of heat. In using the apparatus, the first step is to heat up the four chambers A, A<sup>1</sup>, A<sup>2</sup> and A<sup>3</sup>. To this end, gaseous fuel is admitted by one and air to burn it by the other of the two divisions of one

chlorine. When the charge in A, A<sup>1</sup>, etc., has been sufficiently decomposed, the residual solid product is discharged by the doors c, and after closing these, as well as the pipes M and M' and the sight-holes d, the apparatus will be ready to be heated up again for another operation. The products of combustion after having been employed to heat up an apparatus according to this invention should be applied for evaporative purposes, since the chlorides from which the free chlorine is to be

FIG 1.

set of regenerators RR. The pipes M and M', the discharging doors c, the covers B and the sight-holes d being all closed, products of combustion then traverse each of the four chambers successively, and finally pass off by the other set of regenerators, from which they are conducted

FIG 2

to a chimney. In order to heat the furnace uniformly, the course of the fire-gases is reversed more or less frequently. When the masses of brickwork of the four chambers have absorbed sufficient heat, the admission of fire-gases is suspended, and the chambers are charged by the openings at B with the substance from which chlorine is to be evolved. One of the pipes M and M' is

FIG 3

then opened, and the regenerator on the same side of the apparatus closed, and air only admitted by the other regenerator. The substance will take up heat from the brickwork, and a current of air, which has been previously heated during its passage through the regenerator, will pass over and through the contents of the four chambers, and there will pass off a mixture of gases containing free

evolved will be first obtained in aqueous solution, which solution will require to be evaporated to dryness before being subjected to the action of heat and air in the chambers.—S. II.

*Improvements in the Method of and Apparatus for Treating Bisulphate of Soda for Industrial Purposes.* Frank Wirth, Frankfurt-on-Maine. A Communication from Hermann Herberts, Barmen, Germany. Eng. Pat. 3323, November 10, 1884.

Two cisterns containing respectively a concentrated solution of bisulphate of soda, and chalk suspended in water, communicate with a lead-lined, boiler-shaped vessel, by pipes fitted with taps, and reaching to the bottom of the latter. The lead-lined vessel is provided with a stirrer, and has also a dome from which one pipe leads away through two calcium chloride washers to a gasholder, and another pipe communicates with a vessel containing carbonic acid under a pressure of six atmospheres. Below is a filter communicating with the lead-lined vessel by a pipe also reaching to the bottom of the latter. A portion of the contents of the two first-named cisterns are run into the mixing vessel and agitated. Carbonic acid is evolved and passes away to the gasholder. When all the free acid is saturated, the carbonic acid under pressure is admitted, and drives the turbid contents of the mixing vessel over on to the filter below. The liquor passing from this is concentrated for the recovery of Glauber's salts.—A. R. D.

*Improvements in the Manufacture of Bichromate of Soda.* E. P. Potter and W. H. Higgin, Little Lever, near Bolton. Eng. Pat. 5552, November 12, 1884.

THE salts thrown out from the chrome-liquor (referred to in Letters Patent No. 587, and No. 3329 of 1883) on concentration, are washed with hydrochloric acid in the cold. The sodium chloride remains behind, while the acid liquor contains the chromates in solution, and is used for bichromating further quantities of vat liquor.—A. R. D.

*Improvements in Apparatus for Generating and Hydrating Sulphur Dioxide and like Gases and Vapours, partly applicable to Purifying other Gases.* A. M. Clark, London. Communicated by W. Maynard, New York City. Eng. Pat. 6982, Nov. 17, 1884.

THE sulphur is burned in cups contained in a chamber to which air is admitted through a funnel-shaped inlet,

having the inner end the smaller. A goose-neck pipe leads from the top of the chamber to a closed box provided with a funnel delivering into another box below. Water is delivered by a pipe into this funnel, which has grooved sides, so that the liquor running round, as well as downwards, forms a vortex, and draws away the vapours brought from the burning chamber by the goose-neck pipe. The gases, which are not absorbed by this washing, pass into the lower box. A pipe in the upper portion of this allows for the escape of the insoluble gases, the said pipe being provided with a scrubber of lime or other suitable material, to free the gases from all trace of acid vapours. To increase the efficiency of the water funnel as an aspirator, it may be revolved mechanically if necessary.—A. R. D.

*Improvements in the Manufacture of Ammoniacal Salts, and in the Purification of Gas.* A. McDougall, Penrith. Eng. Pat. 15,496, November 25, 1884.

SULPHUROUS acid gas, as obtained from a sulphur or pyrites burner, is forced through ammoniacal liquor, which also becomes concentrated by the passage of the hot gases. The ammonium sulphite which crystallises out, is oxidised in the air to ammonium sulphate. The solution of acid ammonium sulphite is used to wash coal gas, whereby ammonia is absorbed, and the sulphur compounds are decomposed, and sulphur separated, which latter is used in the burner as a source of sulphurous acid for the continuation of the process.—G. H. B.

*Improvements in the Manufacture of Bichromate of Potash and other Chromates.* Sidney Pitt, Sutton, Surrey. Communicated by Henry Bower, Philadelphia. Eng. Pat. 4102, November 27, 1884.

IN the ordinary process for the manufacture of chromates, whereby chrome ore is calcined in an oxidising furnace, with calcium hydrate or carbonate and the hydrates or salts of potash and soda, and the resulting mass lixiviated, a large percentage of the chromic acid being in a state of complex combination with iron, alumina and lime, obstinately resists solution. The present invention is for accomplishing this solution, by adding an alkaline carbonate to the mass in lixiviation, and then passing carbonic acid through the same. By this means all the chromic acid may be obtained in solution. A slight excess of carbonate—about five per cent.—must be used over and above the quantity equivalent to the as yet insoluble chromic acid, and the carbonic acid used must of course be free from all traces of sulphurous acid.—A. R. D.

*Improvements in the Manufacture of Alkaline and Alkaline Salts.* Sidney Gilchrist Thomas, Westminster. Eng. Pat. 4268, November 28, 1884.

IN the manufacture of alkaline phosphates and silicates from alkaline chlorides or carbonates, by treatment with molten phosphoric or silicious iron, in a basic or neutral-lined reverberatory furnace or converter, the reaction is accelerated and excessive volatilisation prevented by the present invention, which consists in mixing the chloride or carbonate with magnesia, lime, oxide of iron, or oxide of manganese, and compressing or fusing the mixture into bricks.—A. R. D.

*Improvements in and relating to the Manufacture of Salt from Brine and Apparatus therefor.* G. C. Denison and J. E. Higgin, Eureka Salt Works, Anderton. Eng. Pat. 4452, December 4, 1884.

A SYSTEM of pipes is so placed under the evaporating pan that the brine passing through the same on its way to the said pan, receives the heat of the furnaces, and thereby, to a certain extent, protects the pan bottom from burning. The pipes are arranged in rows across the flues, and have their ends connected by H-shaped junctions, the outside ends of which are closed by blank flanges or removable plugs, to make the whole length

of each pipe accessible for cleaning. One end of the pipe system communicates with the pressure main or an elevated cistern supplying cold brine, and the other end delivers into the pan. This outlet is of diminished area to keep the brine in the pipes under pressure. The supply is preferably so regulated that the brine is delivered into the pan at a temperature just above boiling point.—A. R. D.

*Improvements in the Treatment of Chloride of Sodium for the Production of Bleaching Powders and other Materials therefrom.* W. S. Richardson, Gateshead, and W. J. Grey, Gateshead. Eng. Pat. 4417, December 5, 1884.

SOLUTION of sodium chloride is decomposed by an electric current. The chlorine evolved is used for making bleaching powder, the caustic soda is used as such or converted into carbonate, and the hydrogen is available for fuel. For the production of chlorine and metallic sodium, the fused chloride must be substituted for the solution of the salt.—A. R. D.

*Improvements in the Manufacture of Chromates and Bichromates.* W. J. A. Donald, Hillhead, Glasgow. Eng. Pat. 4511, December 15, 1884.

THE ordinary process for the manufacture of chromate of potash is followed in its first stages, with the exception that for the potash salts the sulphate, carbonate, or hydrate of soda is substituted. On lixiviating the batches from the chrome furnaces, a mixed solution of chromate of soda, sulphate of soda, etc., is obtained. To eliminate the sulphate, barium or calcium chloride is added, which causes an insoluble sulphate to precipitate, and leaves chloride of sodium in solution with the chromate. These may be separated by taking advantage of their different solubilities. To obtain sodium bichromate, sufficient sulphuric acid is added to the chromate to combine with half its soda. It is unnecessary to eliminate the sulphate present before this treatment, because it can be removed afterwards together with that formed on the addition of sulphuric acid to the chromate, as described above.—A. R. D.

*Improvements in the Manufacture of Chromates and Bichromates.* W. J. A. Donald, Hillhead, Glasgow. Eng. Pat. 5948, December 15, 1884.

THE almost pure chromate of soda prepared as per application 4511, bearing even date with the present, is treated with its equivalent quantity of caustic lime, whereby chromate of lime is precipitated, and caustic soda remains in solution. These are separated by a hydro extractor or filter press. The chromate of lime may be converted into bichromate by treating it with the equivalent of sulphuric acid to combine with half the lime, and evaporating until the sulphate of lime precipitates out, when it is removed by suitable means. The remaining solution, evaporated to dryness, gives very soluble and pure bichromate of lime.—A. R. D.

*Process for Gilding Pottery.* Ding. Polyt. Journ. 255 [3], p. 126.

THE "Immenaner Porzellanfabrik" in Immenau (Germ. Pat. No. 29566, February 15, 1884) gives the following process for this purpose. After a preliminary heating (to a red heat) a paste of gum and porcelain metal is applied by hand or otherwise, so as to form a pattern—i.e., only the portions which are to be gilded are covered with the paste. The articles are dusted with powdered glazed porcelain and then dried until the small fragments dusted on are held by the gum paste. The articles are then burnt up and after cooling the raised parts (the so-called "Decor") are painted with gold, silver or other metallic colours and then the goods are fired as usual in the muffle. When finished the raised parts appear either biscuit or shining.—H. A. R.

*Action of Dilute Acids on Bottle-glass.* Dingl. Polyt. Journ. 255 [3], 127.

IN a manufactory of artificial effervescing wines it had been noticed that all wines bottled from a new delivery of bottles turned turbid. E. Egger (Archiv für Hygiene, 1884 p. 68) tested the behaviour of various bottles towards dilute tartaric, hydrochloric and sulphuric acids and found that in some bottles the acid was reduced in quantity to a considerable extent in a short time. The analysis of two bad bottles (I. and II.), two pretty fair ones (III. and IV.), and two good ones (V. and VI.), yielded the following results:—

No.	SiO <sub>2</sub>	Fe <sub>2</sub> O <sub>3</sub> +Al <sub>2</sub> O <sub>3</sub>	Mn	CaO	MgO	Na <sub>2</sub> O	K <sub>2</sub> O
I.	53.15	13.14	Traces	11.69	0.81	11.83	3.21
II.	52.90	12.85		15.88	0.95	11.27	3.16
III.	56.31	11.31		16.05	1.15	11.11	3.16
IV.	55.02	12.11		16.21	1.01	12.11	3.59
V.	62.95	6.80		16.72	1.80	9.26	1.10
VI.	57.16	11.79		11.79	0.90	15.41	2.72

A good glass-making mixture should contain enough SiO<sub>2</sub> that the fifth or sixth silicate of the alkali metal and the simple or double silicates of other oxides may be formed. For alumina we must assume the third silicate which softens at a white heat. Besides these there must be present a sufficient quantity of amorphous silicates to prevent devitrification. None of the above samples of glass contains enough silica for forming compounds which can be termed completely proof against acid fluids.—H. A. R.

*Contributions to Our Knowledge of Cements.* Dingl. Polyt. Journ. 255 [2], 76-79.

WHEN cements are treated with water, H. Lechatelier (*Revue Industrielle* 1884, p. 452) finds that not only does calcium hydrate dissolve out but many other compounds. It is best then to use the least possible amount of water. He further notices that cements which have hardened quickly contain only a little free lime, when slowly a large quantity. By the gradual treatment of cements with water he thinks various compounds of lime with ferric hydrate, alumina and silica are formed in the solution. His analysis shows that these oxides are present in a litre of water in the proportion of the following theoretical compounds:—

	Grammes.
CaO.H <sub>2</sub> O.....	1.3
Fe <sub>2</sub> O <sub>3</sub> .4CaO.12H <sub>2</sub> O.....	0.6
Al <sub>2</sub> O <sub>3</sub> .4CaO.12H <sub>2</sub> O.....	0.6
SiO <sub>2</sub> .CaO.3H <sub>2</sub> O.....	0.05

And he considers that these compounds, therefore exist in the cement.

Ed. Laudrin (*Compt. Rend.* 1884, 98, 1053) has formed mixtures of lime and silica in proportions equivalent to the various silicates. A mixture of 3CaO+SiO<sub>2</sub>, when heated to whiteness hardens by the action of either water or carbonic acid—he calls it "Pouzzo-Portland." A mixture of 2CaO+SiO<sub>2</sub>, only once yielded a porous mass having hardening properties when treated in the same way. Similar unsatisfactory results were obtained with CaO+SiO<sub>2</sub>, which only after prolonged heating yielded a mass which set with difficulty and did not harden under water.

De Perrodit (*Génie Civil*, 1884, 6, 30) found that a sample of Longuetty and Co's Portland cement had the composition:—

CO <sub>2</sub> .....	23.8
SiO <sub>2</sub> .....	1.3
Al <sub>2</sub> O <sub>3</sub> .....	8.9
Fe <sub>2</sub> O <sub>3</sub> .....	2.0
CaO.....	63.6
MgO.....	0.4
	100.0

When exposed to air or water it increases in hardness and absorbs water. The power of resistance of the mortar was greater under water than in air.—S. R.

*A Method for Estimating Alumina in Cements.* H. Prounier. Journ. de Pharm. et de Chem. 5, 87.

THE cement is warmed with dilute nitric acid and the liquid treated with ammonia solution till neutral, using tropæolin as indicator. A known volume of semi-normal ammonia solution is then added, the solution diluted to a fixed volume and filtered. Part of the filtrate is titrated back with semi-normal nitric acid thus giving the amount of ammonia used to precipitate the iron and aluminium. The amount of ferric oxide present in the cement is determined by potassium permanganate, the difference then gives the amount of alumina.—S. R.

*Artificial Marbles, Granites, etc.* J. B., W. S. and E. S. Shaw, Stafford. Eng. Pat. 386, January 2, 1884.

CLAY, cement or plaster is rolled, run or beaten out on a board or slab, into a "bat" of the desired size and thickness, which is then dried until it cracks in different directions. The cracks or fissures are now filled up with coloured clay, metallic and other colours, and water, etc., the bat being finally fired in the usual way.—E. G. C.

*Improvements in the Manufacture of Marble.* A. Guattari, Paddington. Communicated by Michele Soderini, Florence. Eng. Pat. 2610, February 2, 1884.

THIS invention relates to the manufacture of marble from sulphate of lime or gypsum, of which the several natural varieties may be used for the purpose—viz., selenitic or sparry gypsum, lithoidal, massive or compact gypsum, anhydrite, pulverulent selenitic sulphate of lime, and fibrous, saccharoid, or calciferous gypsum. The first operation is the dehydration of the gypsum, which is effected in suitably constructed stoves, the temperatures of which vary with the different species of gypsum, from 50° to 244° C. The dehydrated rock is then hardened by being placed in a bath, consisting, as the case may be, of silicate of lime, sulpho-silicate of potash, acid fluo-silicate of potash, double silicate of potash and manganese, etc. Among the other substances employed are chloride of lime, sulphate of potash, phosphates of lime, soda, and potash, borax, etc. The material undergoes a second dehydration after being taken out of the bath. A second bath is frequently requisite, followed by a final process of dehydration. Various colours are imparted to the marble by the use of the following: Cadmium sulphate, yttrium chromate, and lithium chromate, which furnish yellows; dragon's blood, scarlet madder-root, sesquioxide of iron, and didymium sulphate, which give reds; salts of copper, which produce blues and greens; and other compounds.—E. G. C.

*Improvements in the Manufacture of Marble.* Augusto Guattari, Paddington. A communication from Michele Soderini, Florence. Eng. Pat. 2787, February 5, 1884.

SCULPTURED objects in alabaster are hardened and converted into artificial marble by being heated to 37.5° to 50° C., and then immersed in a solution of 8 parts borax, and  $\frac{1}{2}$  part potassium biphosphate, in 100 parts of water, at 22.5° C. After immersion in this solution, the objects are again heated in a suitable stove, this time to a temperature not exceeding 150° C.; lastly, they are allowed to cool, and then again immersed in a solution of borax, to which is added nitric acid, varying in quantity from 50 to 30 per cent. of the water of the solution. The process may be modified by substituting oxalic for nitric acid, and by finally rubbing the objects with a mixture of Canada balsam and naphtha.—E. G. C.

*Imitation Marble.* Augusto Guattari, Paddington. Communicated by Michele Soderini, Florence. Eng. Pat. 2847, February 6, 1884.

SCULPTURED objects in gypsum are dehydrated and coloured in one operation, by being immersed in a hot preparation of bitumen of suitable strength. A hard imitation marble, of a fine black colour throughout, is thus obtained.—E. G. C.

*Improvements in Brick Kilns.* H. J. Alison, London. A Communication from S. W. Underhill and G. E. Fisher, Rochester, N.Y., U.S.A. Eng. Pat. 13,260, October 7, 1884.

This invention consists in the construction of a "permanent base" of a brick kiln—i.e., "a system of furnaces, flues, and reservoirs permanently constructed to support the pile of unburned bricks," the objects being "to obtain a greater percentage of perfectly burned bricks than results from the ordinary methods of burning; to secure economies and durabilities in construction; and to save labour and fuel." The brick kiln base is constructed of fire-clay, or other suitable material, moulded *in situ* by means of removable moulds or forms, and is furnished with a series of passages or hot air reservoirs, which extend through from one side to the other. From these reservoirs lead upwards a number of flues, the end flues being larger than those located nearer to the centre of the kiln-base.—E. G. C.

*Improvements in the Manufacture of Artificial Stone.* J. Hatfield, Kew. Eng. Pat. 14,621, Nov. 5, 1884.

To a mixture of one part hydraulic cement, one part crushed granite, and three parts blast-furnace slag, with a suitable quantity of water, the inventor adds one part of the substance known as slag-wool; the result is said to be a strong, tough, and durable stone.—E. G. C.

## X.—METALLURGY, MINING, Etc.

*On the Employment of Different Kinds of Fuel in Blast-Furnaces.* Dingl. Polyt. Journ. 254 [4], p. 167-177.

H. FEHLAND (*Stahl und Eisen*, 1884, pp. 331 and 497) publishes some investigations on the time which a charge requires for passing through a blast-furnace. A certain Rhenish works, making white pig-iron, charges their furnace in 24 hours 40 times; each charge consisting of

375 tons ore .....	(1cb.m. = 1900kg.) = 1.97cb.m.
125 " lime .....	(2 " = 1500kg.) = 0.83 "
170 " coke .....	(1 " = 150kg.) = 1.20 "
7.00cb.m.	

The cubical contents of the furnace is  $C = 232\text{cb.m.}$ ; the latter therefore holds 33 charges, but as the charge sinters together,  $\frac{1}{2}$  of the whole, or four more charges can be added. The time of passage for that furnace would therefore be 22 hours. A Westphalian works makes 34 charges, each of

320 tons ore .....	1.68cb.m.
178 " lime .....	0.73 "
165 " coke .....	3.67 "
6.08cb.m.	

The cubical contents is here  $C = 164\text{cb.m.}$ ; it therefore holds 304 charges, and the time of passage is 21 hours. An Austrian works has 22 to 24 charges, each of

672 tons ore .....	3.62cb.m.
178 " lime .....	1.13 "
380 " coke .....	10.13 "
11.88cb.m.	

$C$  is equal to  $253\text{cb.m.}$ ; it can hold 19 charges, and the time of passage is 19 to 21 hours. A far shorter time of passage can be attained at the cost of a larger consumption of coke. A Styrian works, working their furnace with charcoal, allow the charge to remain in the

furnace for 14.7 hours. It further appears that for making

Iron rich in phosphorus	the time of passage for a charge is	18 hours.
Thomas-iron .....		17 "
Spiegel .....		17 "
Iron for casting purposes		36 "

J. L. Bell read a paper at the meeting of the Iron and Steel Institute on the use of coal in blast-furnaces (*Iron*, 1884, vol. 23, p. 373). This paper would lose much of its importance by being abstracted.

F. Kupelwieser (*Oestr. Zeitschr. f. Berg. und Hüttenwesen*, 1884, p. 9) discusses the use of brown-coal in blast-furnaces. It can be employed either in the raw state, or coked, or by gasifying it and conveying the gases into the furnace. However, it can never be used by itself to replace coke, and after an extensive series of experiments it has been found that one part of brown-coal must be mixed along with three or four times its weight of coke. A host of investigators tried to convert brown-coal and lignite into coke, so that it could be employed exclusively in blast-furnaces, but all their efforts failed on account of the coke breaking up in small pieces, when exposed to heat. Others tried to obviate this evil by applying a substance which was to cement the pieces, and, indeed, W. Reuss and A. Hofmann seem to have lately solved the problem in this manner. Their process, which is kept secret, is worked at Stillweg, and of a charge of 2100kg. brown-coal, 56% is obtained in large lumps, and only from 30 to 40kg. in smalls.

W. Schmidhammer publishes a calculation on Boll's process for the use of water-gas in blast-furnaces. Supposing that 1kg. coal yields 1.53cb.m. water-gas, consisting of equal parts of carbonic oxide and hydrogen, the author calculates that 100kg. iron require 87.12kg. gas, for which production 57.15kg. coal are required. If carbonic oxide and hydrogen take an equal share in the reduction, and the relation of carbonic acid to carbonic oxide in the furnace waste-gases be equal to 0.63, the following calculation for 100kg. iron would throw a light on the economy of the process.

40.4kg. gas are required for the reduction of the roasted ore. The gas, consisting of 37.7kg. carbonic oxide and 2.7kg. hydrogen, burns to 59.2kg. carbonic acid and 24.0kg. water. For the reduction of 100kg. iron from their combination with 42.85kg. oxygen  $42.85 \times 3983 = 170671$  calories are consumed.

10.1kg. gas yield $40.4 \times 5680 = 229,472\text{cal.}$
Less 10 " loss = 22,917 "
Leaves for disposal = 206,555cal.

The process of reduction therefore shows an excess of 206,525 - 170,671 = 35,854cal. To heat up and fuse the iron and the slags formed, are required:

For 100kg. iron .....	30,000cal.
" 30kg. slags .....	13,500 "
Total .....	43,500cal.
And to keep the mass in a fluid state, and for losses .....	46,500 "
Grand total .....	90,000cal.

which can be produced by the combustion of  $\frac{206,525}{23,140} = 15.8\text{kg.}$  gas, with a blast  $800^\circ \text{C.}$  hot. The 15.8kg. gas consist of 14.7kg. carbonic oxide and 1.04kg. hydrogen. The products of combustion are  $\frac{14.7 \times 14}{28} = 23.1\text{kg.}$  carbonic acid and  $9 \times 1.04\text{kg.}$  water. The oxygen taken from the blast therefore amounts to  $23.1 + 9.39 = 15.8 = 16.69\text{kg.}$ , which are mixed with  $\frac{16.69 \times 77}{23} = 55.8\text{kg.}$  nitrogen. The quantity of air required is therefore  $16.69 + 55.8 = 72.49\text{kg.}$  The carbonic acid in the waste-gases amounts to

Produced at the tuyeres .....	23.1kg.
" by the reduction of ore .....	39.2kg.
Total .....	82.3kg.

The waste-gases are supposed to contain an equal quantity of carbonic oxide; the furnace therefore requires an excess of  $\frac{82.3 \cdot 100}{93.3} = 88.1$  kg. gas. The total quantity of gas required now amounts to  $15.8 + 40.4 + 88.1 = 154.3$  kg., for which production  $\frac{164 \cdot 154.3}{25} = 101$  kg. coal are wanted.

The heat of the waste-gases and other small sources of loss or production of heat were left out of consideration in order to simplify the matter. It will, of course, be necessary to compare these figures with results obtained by the actual working of the process. From a practical point of view it appears probable that the work in the furnace will be rendered more difficult on account of the column of ore not being kept loose, owing to the absence of coke. The same circumstance will also offer difficulties to the passage of the gas, especially as there must be in some place of the furnace a zone where the slag is not yet in a fused state, but already sufficiently soft to resist the passage of the gas.—S. II.

*The Utilisation of the Waste Gases of the Blast Furnace.*  
Dingl. Polyt. Journ. 254 (6), 254, 1884.

ANALYSES of blast furnace gases, published by Bunsen in 1839, showing that these contained considerable amounts of carbonic oxide, methane and hydrogen, confirmed the opinions advanced by Aubertot, Curadaw and others, that these gases possessed considerable value as

special attention being paid to improvements in and inventions of plant and processes described or patented in 1884.

The applicability of blast furnace gases to heating purposes, is lessened by the presence of blue-dust, water vapour and carbonic acid. For the elimination of blue-dust, Selradner and Macco (Ger. Pat. 28,063, January 13, 1884) allow the waste gases to pass from the cone into a wide chamber A (Fig. 1), where, from the velocity of the current being decreased, the larger portions of ash are separated from the finer, and fall into the furnace. The fine dust is collected in the compartments of the tube arrangement CD, through which the gases take the circuitous course indicated by the arrows. In Fig. 2 a box arrangement is shown, which may be substituted for the tubular system of Fig. 1. The filtration of the gases through slag-wool, is recommended by K. Moller; if sufficient surface of this be supplied to cool the gases below  $100^\circ$ , a portion of the aqueous vapour, and likewise tar and ammonia, if coal had been used, are collected. The co-application of water assists the condensation of ammonia. Cooling and washing chambers, devised by Alexander, as employed at the Gartsherrie Iron Works, and by means of which one ton of ammonium sulphate is recovered daily from the gases of two blast furnaces, are described by Lürmann (*Stahl und Eisen*, 1884, p. 35), and are illustrated by Figs. 3 and 4. The gases pass from the furnace by the main pipe G, through pipes g, the number of which is proportioned to the temperature and

fuel, and gave an impetus to research, as to the best methods for their utilisation. A historical summary of the most important work upon the subject is here given,

amount of the gases, into the coolers K, consisting of series of upright tubes, connected with each other alternately, above and below, so that the gases take the course

indicated by the arrows. Cooling is effected simply by reason of the large surface exposed by the pipes to the air. The pipe which connects the lower ends of these tubes also serves to collect condensed liquids, tar and ammonia water; these are not permitted to rise to such

water trickles from *w* down these shelves; the tar and ammonia, which have escaped condensation in *K*, are so collected, and pass from *W* into *T* and *S*. The watery liquid, which collects in *S*, is pumped by *P* to the top of the towers, and used repeatedly, until sufficiently enriched

a height as to obstruct the passage of the gas, but are drawn off by the overflow pipe *u*, to the tank *T*. The gases pass through *z* into the washing towers *W*, provided with perforated shelves of wood or metal; a stream of

with ammonia. The cooled and washed gases proceed by *x* to the second main *G*, to be utilised as required. If it be desired simply to eliminate flue dust, the towers are unnecessary; but it is advisable in such a case to moisten

the gases before they enter the coolers. Belani advocates the arrangement illustrated in Fig. 5, for moistening the flue dust; steam is passed into the main pipe G, the moistening being completed by the application of a water spray in A, at the bottom of which chamber the wet dust collects. The cooling space K is divided into compart-

ments by partitions *h*, down the sides of which streams of water flow, and effect the cooling of the gases, which pass up and down the spaces *k*. In Figs. 6, 7, 8, are given respectively the plan, elevation, and front view of the large cooling and washing chamber, devised by J. Alexander. Each chamber K is divided vertically into two

two vertical compartments K, oppose to the gases a surface of 2200 square meters, cooled by water; and one of 500 square meters cooled by air only. The gases leave the horizontal compartments by the short tubes *o*, thence pass into the upright pipes *p*, leave these at the bottom

by *q*, and are thence led into the towers W, provided with perforated shelves of wood or metal, which are so fitted that the gases pass at each shelf from one side of the tower to the other, depositing any residual tar.

compartments; these again, each horizontally, into four. The gases pass from the main G through the vertical pipe *g*, thence by the horizontal connections *a* into the compartments. Extending the whole width of the compartments, and riveted to the walls thereof, are rectangular

Fig. 10.

by *q*, and are thence led into the towers W, provided with perforated shelves of wood or metal, which are so fitted that the gases pass at each shelf from one side of the tower to the other, depositing any residual tar.

The rectangular wash tower W, shown in Figs. 9 and 10, with sloping shelves, is an improvement upon those of circular section, as the gases are distributed more evenly. The man-holes *m* are the more easily reached by the steps *t* outside the tower. The shelves are cleansed from tar by passing steam in the tower by *d*. This tower

has a cubic contents of about 720cb.m., an outer surface of about 480 square meters; the shelf surface is in all about 560 square meters.

A cylindrical cooler, shown in Figs. 11 and 12, has likewise been devised by Alexander. Within the large cylinder K, seven smaller cylinders *k* are placed. These

Fig. 12.

are connected with each other alternately, at top and bottom, so that the gases from G take a circuitous course to *g*. Within each small cylinder, seven pipes are fitted; these are open to the large cylinder K, which is filled with water. The cold water enters at W, the warmed

fig 13

flows away by *w*, liquids condensed from the gases are withdrawn by *u* and *z*. The surface cooled by water is about 1700 square meters; that cooled by air 288 square meters; and if necessary 2000 square meters of surface, cooled by water, can be obtained.

fig 14

To increase the yield of ammonia, from blast furnaces using coal, it is proposed to introduce steam at numerous points within the cone, 2 or 3m. below the mouth.

An arrangement for this purpose is shown in Figs. 13 and 14. Or the steam may be introduced by a single jet in the centre; and if desired can be superheated by allowing the steam supply pipe to pass for some distance in the interior of the pipe conveying away the waste gases.

Fig 15

The arrangement of pipes shown in Figs. 15 and 16 has been devised by Körting Bros., and is equally applicable to the cooling as to the washing of the waste gas. The tubes are arranged in three ranks; and connections between the individual pipes of each rank are so made that the gases pass up through one set of five pipes and down through the next. A system of 450 tubes of 300mm. diameter, and 3.5m. in length, gives a total surface, cooled by the air, of 1700 square meters. An injector may be advantageously applied at different points of such a system.

Fig 16.

The large washing chamber, devised by Young and Beilby, built of masonry, shown in Fig. 17, affords a means of decreasing the velocity of the stream of gas, and of thus allowing a complete separation of tarry matters. The gases are introduced by the conduit *g*, and enter the chamber by the openings *c*, covered by leaden bells. A fine rain of water, acid, or acidified water, is maintained during the passage of the gas. The washed gases pass away by *G*, the washings by *a*.

A somewhat more advantageous arrangement is that shown in Fig. 18. A series of such chambers may be built on different levels, so that the liquid employed for washing being introduced at the opposite end of the system to that at which the gas enters, passes simply by gravity through the whole series, until spent. The dis-

advantages of having to pump the liquid to the top of the chamber and there spray it, is obviated by the above plan. The size of the chambers is advantageously such that for 100cb.m. of gas passed through in twenty-four hours, at least 0.5cb.m. of space is provided. Large chambers, in which the cooled gases can come to rest and

up of the charcoal or coke are similar to ordinary generator gas; and, therefore, need not be lost. Blast furnace gases regenerated according to this plan, may be advantageously

employed in the Siemens-Martin process. The following analytical results permit of a comparison between

Fig. 20.

ordinary generator gas and blast furnace waste gas, ordinary and regenerated:—

GENERATOR GAS FROM			BLAST FURNACE GAS.		
Coke.	Coal.	Ordinary.	Completely Regenerated (theory)	Practically Regenerated	
CO .... 33.8	25.0	21.23	42.42	31.87	
CO <sub>2</sub> .... 1.3	6.5	20.60	0.00	8.37	
Hydro- carbons } .... 1.5		0.38	0.21	0.28	
H ..... 0.1	0.5	0.21	0.15	0.18	
N ..... 61.8	60.5	51.58	57.22	56.30	
Total .. 100.0	100.0	100.00	100.00	100.00	
1 kilo of gas yields calories			841	920	923
			688	1087	

F. Lürmann proposes to employ this regenerated gas in the blast furnace. The gases of the reduction zone would, in this case, contain less nitrogen than when, as usual, the carbon is gasified by direct combustion with atmospheric air.—W. D. B.

*Method for the Manufacture of Malleable Nickel and Cobalt.* Dingl. Polyt. Journ. 1884, 254, 315.

NICKEL or cobalt (according to a statement of the Berndorfer Metallwaaren-Fabrik, Ger. Pat. 28,989, January 15, 1884), when in a melted state, take up carbon and oxygen simultaneously, the greater part of the latter being given off again on cooling, leaving the

deposit their particles of tar, appear to be most suitable for the complete separation of the tar.

For the regeneration of blast furnace gas,—i.e., the reduction of carbon dioxide to the monoxide, Ehrenwerth recommends the employment of the shaft furnace, shown in Figs. 19 and 20. This is filled, through F, with coke, wood charcoal, or the like. Through the pipe *v*, and tuyères *r*, air can be supplied. Through the pipe *g* and mouths *c*, the waste gases enter the furnace. The mouths permitting the gases to enter, may be 10 or 20cm. above or below the air tuyères, or even side by side with these, in which case they should have a wide section. If intermittent work is alone desired, the coke or charcoal is first brought to a sufficiently high temperature by the application of the air blast, which is then almost shut off, and the waste gases allowed to stream through until the temperature has fallen to such an extent as to render regeneration imperfect. The gas is now shut off, and the air blast again applied, and so on. For uninterrupted work, two regenerators, at least, are required. It is pointed out that the gases obtained during the heating

metal in a porous condition. Although by continued melting in graphite crucibles, under a cover of charcoal, the oxygen may be entirely expelled, the metal takes up the more carbon the longer it is kept in a melted condition, and thus becomes more and more brittle. In order to overcome these difficulties, the oxides of the metals are reduced at a moderate heat, and the porous cubes obtained immersed in a 4 per cent. solution of an alkaline manganate or permanganate. After drying they are melted, whereby the carbon is oxidised, the metal at the same time taking up a small quantity of oxygen. To get rid of this, a small quantity of black flux (obtained by igniting cream of tartar in a covered crucible) and some charcoal is added as soon as the metal flows freely. By the combined action of the charcoal and the potassium vapours generated from the black flux the oxygen is quickly removed. Instead of black flux aluminium, calcium, calcium-zinc, in quantities of one-tenth per cent. of the metal or mixtures of two or more of these materials in combination with charcoal may be successfully employed for the purpose of removing the last traces of oxygen. Enough charcoal is added to form a layer on the surface of the molten metal, through which the deoxidising metals are introduced. —F. M.

*The Preparation and Application of Weiller's Silicon-Bronze.* Dingl. Polyt. Journ. 234 [12], 492.

IN the *Bulletin de la Société Industrielle de Marseille*, 1882, p. 150, appears a paper by X. Müller, engineer to L. Weiller, of Angoulême, from which the following information has been taken:—

The oxide present in a mass of metal or alloy occasions an absence of homogeneity, which is fatal to the qualities regarded as essential. Experiments in Weiller's factory have established this, especially as regards the production of wire required of good conductivity and strength for electrical purposes. Carbon was found to be unfit for preparing a metal free from oxide, because an excess of carbon proved still more deleterious, and was unavoidable. Phosphorus gave better results, but traces of phosphorus in the metal lessened its conductivity and made it brittle; phosphorus being applicable only where resistance to impact or friction is desirable.

The advantage of using silicon has been already shown by Sainte-Claire Deville, but its cost was too great for general application. After three years' research, L. Weiller has obtained satisfactory results. Potassium silico-fluoride in presence of sodium supplies the silicon which effects the reduction of the oxide in the alloy, which at the same time takes up only traces of the metalloid, the excess floating with the slag. It is only necessary then to pour the alloy into moulds; the cast bars are afterwards turned and drawn in the ordinary way. This process of deoxygenation is applicable to various alloys for different purposes, but especially for electrical connections. The silicon-bronze is well adapted for articles subject to pressure, impact or friction, such as valves, bearings, etc.

The electrical quality of silicon-bronze wire as now delivered by L. Weiller for telegraphic purposes corresponds to the following formula:—From the resistance  $R_0$  at 0° the resistance  $R_t$  at  $t$  degrees is found according to the formula  $R_t = R_0(1 + kt)$ , and for silicon-bronze wire for telegraphs  $k = 0.0039$ , and for telephones  $k = 0.0015$ .

The reason for the difference in the two sorts of wire is that for telegraphs superior conductivity is the principal requisite, whilst the short circuits of telephone wires in towns allow some sacrifice of conductivity for the advantage of greater strength. Telephone wires of this material in Trieste have satisfactorily withstood the most violent storm winds. Complete security is assured with spans of 300 to 350 metres. On account of its strength this material does not require the support of iron wire for sub-aqueous cables of short length.

Tables of comparison with pure copper wire are quoted. Estimations of installations for 1000 kilometres show a saving of over 30 per cent. for silicon-bronze as against iron wire. Its use for telephones

and telegraphs has been found successful in France and Austria by various companies and official departments. —G. H. B.

*On the Influence of the Temperature of Tempering on the Quality and Constitution of Steel.* A. Jaroliméck. Dingl. Polyt. Journ. 255 [1], 1-10; [2], 56-60.

THESE two papers deal with the relations of the various physical properties of steel to one another, and to its chemical constitution. The author shows that the intermediate temperatures to which the steel is subjected, as well as the mechanical processes employed, affect considerably the final hardness and elasticity. An investigation on the specific volume of steel has long been wanted, and without doubt would throw considerable light on many of the difficult problems connected with this subject. The author has previously shown (Dingl. 1876, 221, 436, 518), that the hardness of steel depends on the rate by which it cools down from a definite critical temperature, which for most kinds is somewhere about 500° C. In his previous experiments he determined the hardness obtained by heating the steel to different temperatures, varying from that of boiling water to that of molten zinc. The temper of the steel depends on the time at which it is kept below another limiting temperature.

Strödel and Barns (Würzburg, 1882), in a paper on the influence of the hardness of steel on its magnetic

and other physical properties, have drawn attention to the fact that the thermoelectric, conducting and magnetic properties of a tempered steel wire depend in the same way on the limit of temperature to which it has been exposed. The amount of hardness was determined by taking long pieces of the steel and forming them into spiral springs, which could be then stretched by different weights. In this way the author demonstrates that the limit of elasticity of these springs of steel, as shown by their greater bending and twisting, increases with the amount of heat to which they have been exposed. This limiting temperature is about 300° C, but if after having been stretched, the wire is again heated, the traction power is found to have increased. Experiments are described with the following five operations being varied:—(1), heating the wire; (2), winding the wire into a spiral; (3), heating the spring; (4), stretching the spring; (5), heating the stretched spring.

From these experiments we learn that the elasticity is increased by long stretching of the wire, and that this elasticity is not lost by heating to 300° C. and then slowly cooling. He next discusses the relation of this experiment to the specific volume of the steel, and shows that the specific volume of the steel is of less

practical value than the physical constants above described. The tenacity and solidity of the steel, in the same way, is directly influenced by the hardness, and so by the temperature and time employed in tempering.

W. Lorenz has described (Dingler's, 1880, 235, 183) a method for determining the hardness of hollow bodies. Compression of the steel, when still red hot, by means of two metal plates connected with a hydraulic press capable of giving a pressure of 1000 to 3000 kilols. per square centimetre, causes the solidity to be increased.

The curves in the diagram show the rate of change of temper with increase of time at different temperatures.

The author has found that in some experiments with tools hardened in this way the results obtained were very satisfactory, but considers that further inquiries are needed before the different behaviour of steels can be explained and useful results obtained.—S. R.

*On some New Alloys and their Uses.* Dingl. Polytech. Journ. 256 [2], 73.

TH. FLEITMANN, of Iserlohn (D.R.P., No. 25,924 A., January 6, 1884), has shown that pure nickel and its alloys with copper, cobalt and iron can have other metals added without their losing the property of being welded, and therefore can still be used for making plate. The metals which can be added in this way are zinc, tin, lead, cadmium, iron and manganese up to as much as 10 per cent.; any additions, however, are not of much practical value, as the alloy of 25 parts of nickel with 75 of iron has a white colour, and resists the action of the atmosphere far better than iron alone.—S. R.

*A New and Improved Process and Apparatus for the Extraction of Metals from their Chlorides or Fluorides.* Lorentz Albert Groth, 30, Finsbury Pavement, London. Communicated by Richard Grützel, Hanover. Eng. Pat. 551, January 3, 1884.

THE extraction of certain metals, such as magnesium and aluminium, is to be effected on a large scale by the electrolysis of the fused chloride or fluoride in the presence of a reducing or neutral gas. The negative electrode may be the containing vessel itself or otherwise; the positive electrode (of carbon) is separated from this by a tube of non-conducting material with apertures (or open) at the lower end, but closed above, with the exception of a tube provided for the removal of chlorine or other gases evolved during the process. In close proximity to the positive electrode may be placed rods or plates, composed of the oxide of the metal under treatment mixed with carbon, which should be slightly in excess of the amount required to form carbonic oxide, and made up with tar or dextrine, dried and heated to redness. These serve to regenerate the haloïd compound electrolysed. The whole is closely covered and provided with two tubes, one for the admission and one for the removal of the reducing gas.—W. G. M.

*An Improved Smelting Furnace.* Charles Bramhall, Oughtbridge, near Sheffield. Eng. Pat. 586, January 3, 1884.

THE invention relates to an improved smelting furnace, for reducing iron ore or pig iron, for converting them into steel, and also applicable to smelting furnaces for other purposes. The furnace described in the specification, and illustrated by a drawing, has the general shape of a cupola or blast furnace, fitted with five or a larger or smaller number of tuyeres, and intended to be worked with gaseous fuel. The air and the gas are blown into the furnace by separate blowing engines and separate pipes, and pass each through two sets of receptacles filled with bricks heated alternately on the regenerative principle. The air and gas tubes unite near the inner wall of the furnace. The hot gases escaping near the top of the furnace are led by flues through the regenerators, thence to a chimney. Valves or dampers are introduced for the regulation of the supply of both gas and air.—B.

*A New or Improved Method of Treating Sulphides and Oxides of Metals and Obtaining Products therefrom.* Sir Francis Charles Knowles, of Lovell Hill, Bart., Mayfield, Isle of Wight. Eng. Pat. 7056, Jan. 3, 1884.\*

IN pursuance of this invention, sulphides or oxides of iron are subjected to a full red heat in a closed retort, through which a current of coal gas, peat gas, or petroleum vapour passes, whereby the iron oxide is reduced to a metallic ore, or, on prolongation of the process, converted into a carburet. Ores so reduced are treated in a Bessemer converter with a small admixture of molten spiegel-eisen, and subjected to the blast of a neutral mixture of air and carbonic oxide gas, which process is continued until complete fusion. For the production of a mild steel, a blast with a slight excess of air is used. With appropriate re-agents, and a non-silicious lining, phosphorus, if present, may be eliminated. Ores of other metals may be similarly treated.—B.

*Furnaces for Making Malleable Iron and Steel.* J. Bureh, Stockport, and R. Allen, Manchester. Eng. Pat. 1086, January 9, 1884.

THE present improvements are supplementary to those described in Eng. Pat. 3250, 1882. The principal features of the former invention comprise three sections—viz., a main firegrate, combined with a reverberatory rocking hearth of unusual length, and a balling cylinder which rotates. The new system of continuous puddling consists in feeding a fresh charge of molten metal into the fore end of the furnace every time the hearth rocks to and fro, and the charges are, by the rocking motion, caused to follow each other throughout the whole length of the refinery chamber into the balling cylinder, from the fore end of which these several charges are delivered in the form of puddled balls. The balling cylinder has a downward inclination from the end contiguous to the refinery chamber. The several charges of metal gradually become pasty and coherent, as, by the rotation of the cylinder, they are caused to move along a spiral gutter made in the form of a hollow curve around the interior of the cylinder; by this means all the charges in the cylinder are made to advance one turn of the spiral every time the cylinder rotates, and by degrees they become solid masses, which are gradually rolled in the curved gutter into the form of puddle balls, and which, as they slowly approach the firegrate at the end of the cylinder, are exposed to the increasing "final heat," and the slag becomes highly fluid, so that it readily separates from the puddle balls, and falls through a sloping grid, down which the balls roll to the trolley. The chimney is erected at, or contiguous to, the lowest end of the refinery chamber.—J. T.

*Recovering Tin from Tinned Metallic Surfaces.* A. P. Price, London. Eng. Pat. 2119, January 25, 1884.

THE superficially tinned metals are made to form the anode in a solution of caustic alkali, a dynamo electric machine or other electric generator being employed. The tin being dissolved may be obtained from the solution by electric agency or otherwise, or the resulting stannate may be employed in the arts.—J. T.

*The Extraction of Metals from Carbon, or Substances known as such—namely, Graphite, Coal, Coke, Cinders, and Ashes.* Annie Eliza Scott, South Kensington, London. Eng. Pat. 2162, January 26, 1884.

THE carbonaceous substance is mixed with salt and placed in a crucible in alternate layers with fragments of metal; on heating, the latter fuse and are to alloy with the metals contained in the former. Or the alloying metal (e.g., copper, zinc, etc.) may be first fused and the carbon then added. From the residual soluble silicate any of the alloying metal oxidised is to be recovered.—W. G. M.

\* This patent is either wrongly dated or wrongly numbered—7056, January 3, 1884. At that date the number of patents taken out had not reached much above 600.—B.

*Improvements in Puddling Furnaces.* George Morris and George Slater, both of West Bromwich. Eng. Pat. 3065, February 11, 1884.

THE improvement consists in the introduction of a cast-iron or brick water chamber between the flue-bridge and the flue of the puddling furnace, so arranged that the flame and products of combustion passing from the puddling chamber impinge upon the surface of the water, which is preferably at the same level as that of the brickwork in the ordinary furnace. The supply of water may be obtained from the tool bosh, used by the puddler for cooling his tools. The slag pressed over the flue bridge flows into the water and is granulated. The cooling action of the water prevents the rapid destruction of the flue stack by the hot gases and permits the use of an inferior brick.—W. G. M.

*Improvements in obtaining Aluminium Bronze.* Anthony Adziarski, Brest-Litowsk, Russia. Eng. Pat. 3090, February 11, 1884.

CRYOLITE or other aluminous matter is fused with suitable fluxes in a crucible containing the metal with which the aluminium is to be alloyed (copper, brass, etc.). A current from a powerful dynamo machine is then passed through the liquid mass, using carbon as an anode and the alloying metal itself as the cathode. Silica must be absent or silicon will pass into the metal.—W. G. M.

*Improvements in the Method of Protecting Submerged Structures of Iron and Steel from Corrosion and Foulings.* F. Maxwell Lyte, London. Eng. Pat. 3536, February 18, 1884.

IN a previous communication (Eng. Pat. 3375, of 1883) the inventor showed that it is necessary to interpose between the anti-fouling paint and the metallic iron a coating serving to isolate the anti-fouling paint from the iron so as to avoid the rapid destruction of the former and the corrosion of the latter. Bitumen forms an excellent undercoating both in respect of cheapness and efficiency. The paint is produced by dissolving natural bitumen in turpentine, benzene, or benzoline to the requisite thickness, and adding, if desirable, zinc oxide or hydrosulfide, or glass, porcelain, burnt clay, silica, alumina, magnesia, powdered chalk, or calcareous rock, asphalt, barium sulphate, powdered coal, anthracite, coke or graphite, or the so-called silicate paint, and if considered necessary, drying oils so as to constitute a paint with which the iron is first coated and on which the anti-fouling paint is applied.—D. B.

*Improved Basic Linings for Open Hearth Steel and Iron Furnaces.* William F. Batho, 9, Victoria Chambers, Westminster. Eng. Pat. 3921, February 26, 1884.

THE basic lining is to be mixed with metallic iron (wire, scrap, etc.), in such a way that the metal will act as a bond, and will always form a portion of the wearing surface of the lining.—W. G. M.

*A New or Improved Method of Extracting Metals from the Material found combined with Coal, commonly known as Ironstone.* John Miles, High Holborn, Middlesex. Eng. Pat. 4333, March 4, 1884.

THE coal containing the ironstone is to be burnt and the residue strongly heated for 48 hours in a steel crucible with its own weight of scrap steel. It is then cooled in a closed vessel and the powder and pieces of metal are ready for any purpose to which the inventor may propose to apply them.—W. G. M.

*An Improved Method of Tinning Plates.* By Thomas Henry Johns and William Albert Johns, Clapton. Eng. Pat. 13,235, March 10, 1884.\*

THE invention relates to a method of coating light sheets, generally called "taggers," or ordinary plates, without

passing them through a tinning bath. As an illustration, there may be two baths side by side, the one containing coating metal for treating plates in the ordinary way, the other containing grease, and between the two a pocket also containing grease. Above the pocket the finishing rolls are placed. Plates having passed through the tin bath and into the centre grease pocket, are raised and passed through the finishing rolls, and when several such plates have been treated, they leave the rolls coated with a certain amount of metal. Other plates, such as "taggers," or ordinary kinds, having meantime been prepared in the grease bath; if one of these is now passed through the rolls it will receive a thin coat of metal. The rolls may be supplied or fed with coating metal in any other convenient way.—B.

*An Improved Method and Apparatus for the Amalgamation of Free Gold.* Rowland John Atcherley, of 52, Chancery Lane. Eng. Pat. 4865, March 14, 1884.

THE invention relates to apparatus by means of which the free gold to be saved from gold-bearing slimes, or pulp, is caused to pass through a continuous fine shower of mercury, and is thus brought into such intimate contact therewith as to be thoroughly amalgamated, and thus to prevent the escape of float or flour gold. The apparatus consists of a vat or trough, the bottom of which is perforated with a great number of small holes. The trough is placed above and along the flumes or launders conveying the slimes or pulp, and should be of the same width as the launders. A receptacle is placed at the lower end of the launders for catching and collecting the mercury after passing through the slimes, from which receptacle it is raised again to the perforated trough by means of an elevator, a pump, or in any other convenient manner, thus making the action continuous. Provision is made for collecting the mercury clear of slimes, and for straining off any solid or semi-solid amalgam before returning it to the trough.—B.

*Improvements in the Manufacture of Chromic Compounds.* Sidney Gilchrist Thomas. Eng. Pat. 5130, March 19, 1884.

THE invention relates to the manufacture of chromic compounds from chrome iron ore. The ore is first treated in a blast furnace, in which, by preference, an excess of coke or charcoal and very hot blast are used, so as to produce a pig containing nearly all the chrome alloyed with iron and carbon. This chrome pig is then treated in the molten state in a gas furnace or Bessemer converter having basic or neutral linings, such as lime, magnesia, or chrome iron ore. Into the converter, or furnace, there is introduced a quantity of lime, or of alkaline chloride, or of alkaline carbonate or hydrate, or of magnesia, more than sufficient to combine with the chromic oxide formed by the oxidation of the chromium as well as with any silicon or phosphorus present in the crude iron—potassic or sodic carbonate or hydrate are preferred. A slag consisting largely of alkaline or calcic chlorate is formed, and, after lixiviation with water, the solution is treated for the manufacture of any chrome salt required.—B.

*Improvements in the Manufacture of Sodium.* Sidney Gilchrist Thomas, 9, Palace Chambers, Westminster Bridge. Eng. Pat. 6367, April 15, 1884.

WROUGHT or cast-iron retorts or tubes, with a thick lining of any refractory material unacted upon by sodium—e.g., highly fired lime, magnesia, or dolomite, or graphite are used. Into these the mixture of sodium carbonate and carbon may be fed continuously; through them is passed a current of reducing gas (preferably water-gas) previously heated to a high temperature in small regenerators. The retorts will not require external firing. The gases, charged with sodium vapour on leaving the retorts, are passed through a condensing arrangement, and are then burnt in the regenerators. —W. G. M.

\* The above patent is either wrongly dated or wrongly numbered—13,235, March 10, 1884. At that date the number of patents taken out had not reached much above 1000.—B.

*Improvements in Separating and Obtaining Silver from Metallic Compounds.* Desmond G. Fitz Gerald, Brixton, Surrey. Eng. Pat. 6371, April 15, 1884.

THE argentiferous metal is treated with nitric acid containing an oxidising agent, such as binioxide of lead, or of manganese, to recover the oxides of nitrogen otherwise lost. The silver in solution, as nitrate, is then precipitated as chloride by hydrochloric acid (preferably gaseous), thus leaving free nitric acid in solution, or by calcium, barium, or lead chloride—the nitric acid being afterwards regenerated by treatment with sulphuric acid, or the silver may be thrown down as oxide by calcium or barium hydroxide. The chloride, or oxide, is then deposited in an electrolytic cell, on a negative element of silver, using zinc or iron as the positive metal.—W. G. M.

*An Improved Compound Metal or Alloy, chiefly designed for Deacidifying and Coating Metal Plates.* Henry Harris Lake, Southampton Buildings, Middlesex. Eng. Pat. 6433, April 16, 1884.

THE proposed alloy consists of lead, tin, and zinc, together with a small proportion of sodium, in proportions varying with the use to which the coated metal is to be applied. The metals, after interfusion in a crucible, are ready for use; while fused the mixture is covered with a vegetable oil, or animal fat; it has a very low fusing point.—W. G. M.

*Improvements in Obtaining Copper.* Astley Paston Price, Lincoln's Inn Fields, Middlesex. Eng. Pat. 6722, April 23, 1884.

COPPER is precipitated from solution by finely divided iron, the liquid meanwhile being well agitated by steam, air, or otherwise.—W. G. M.

*A New or Improved Process of Treating Iron.* Alex. Melville Clark, 53, Chancery Lane, Middlesex. Communicated by Russell B. Abbott, of Albert Lea, Minnesota, U.S.A. Eng. Pat. 7940, May 19, 1884.

THE object of this invention is to produce from ordinary wrought iron a weldable iron of superior toughness and hardness. It is to be effected by heating the metal nearly to a welding heat, then rolling it in an intimate mixture of fourteen volumes of sand with one of manganese dioxide and one of common salt, by working, reheating, and repeating the treatment, and finally by again reheating to a weld heat and quenching in water. The mixture may, if preferred, be pressed into contact with the metal by any convenient method other than rolling.—W. G. M.

*An Improved Method and Furnace for Obtaining Crude or Course Copper directly from Copper Ores and Mattes.* Alex. Melville Clark, 53, Chancery Lane, Middlesex. Communication from Jules Garnier, Paris. Eng. Pat. 9498, June 27, 1884.

THE furnace is in the form of an inverted truncated cone, and is mounted on hollow trunnions to facilitate the discharge of its contents in case of emergency. The lower portion of the furnace is lined preferably with a material incapable of being attacked by the basic constituents of the ore—such, for example, as oxides of chromium, natural calcium sulphates, zinc silicate, titanium compounds, bauxite, calcium phosphates, etc.—whilest the upper part is lined in the usual way, the two linings being separated by a zone of refractory clay. If the ordinary lining be used throughout, the lower portion should be very thin and be air or water-cooled. The inert materials are applied in the form of bricks (or in the plastic state), made up with clay, lime, tar, etc. The blast, entering by the trunnions, passes through chambers surrounding the furnace, thus effecting the double object of heating the blast and cooling the furnace walls; thence it passes through tuyeres situated between the tap-hole, which is at the bottom of the furnace, and the slag hole. The ore, or matte, is charged in the usual way, and, when melted, fills the crucible up to the level of the tuyeres; the slag hole is then stopped and the air

blown by high-pressure blast through the accumulating sulphide, resulting in the production of crude copper, which collects in the crucible and is tapped off at intervals; if of sulphur dioxide, which passes off with the blast; and of oxides of metals, more basic than copper, which pass into the slag, and are removed also by tapping. The fusion of the matte may also be effected by a low-pressure blast, introduced above the slag hole, until the sulphide reach the level of the latter, when the high-pressure blast at the lower level is let on.—W. G. M.

*Coating Metal, Glass, Porcelain, etc., with Ornamentation of Aluminium or Aluminium Bronze.* C. D. Abel, London. Communicated by G. Gehring, Landsbut, Bavaria. Eng. Pat. 13,425, October 10, 1884.

ALUMINIUM or aluminium bronze, either in the shape of foil or as powder, is applied to the surface by the aid of the following substances:—Sebacitate of alumina or resinates of alumina—that is to say, alumina soap—is mixed with oil of lavender or other volatile oil and the aluminium. The alumina soap is formed by precipitating a solution of either common soap or resin soap by means of alum. These alumina soaps are dissolved in volatile oils to form a thin lac, which is incorporated with the aluminium, and the mixture is applied to the surface to be coated by means of a brush. The surfaces so treated are then exposed to the open air or to heat, as the case may be.—J. T.

*An Improved Process for Coating Iron or other Metals with Tin, Lead, or Ferroc.* Adolph Gutensohn, Globe Wharf, Mile-End Road. Eng. Pat. 13,560, October 14, 1884.

THIS process consists in the substitution of a hot saturated solution of sal-ammoniac, together with a little hydrochloric acid and glycerine, containing a small quantity of resin, for the grease bath generally used preliminary to the tinning of the pickled plates.—W. G. M.

*Improvements in Treating Copper Matte.* A. W. L. Reddie, Bream's Buildings, Chancery Lane. Communication from John J. and Robert Crooke, of New York, U.S.A. Eng. Pat. 14,853, November 11, 1884.

THE object of the invention is to separate objectionable impurities, such as arsenic, antimony, iron, and lead, and to recover the silver and gold contained in the matte, and to produce a pure copper at a minimum cost. The first or desilvering process is conducted in a reverberatory furnace of 2 tons' capacity, having a tap-hole, and a working and an end door; in front of the tap are a pair of 10-ton iron lead kettles. 3 tons of lead are heated strongly, 2 tons of the crushed matte added, and the mass well rabbled. A partial oxidation of the sulphur, attended by a rise of temperature, now occurs, and the lead alloys with the silver, gold, antimony, and arsenic. After a further rabbling for 15 minutes, 60 per cent. of the added lead separates, and in half-an-hour it is tapped into one of the kettles. A further addition of two tons of lead is now rabbled in for half-an-hour, and tapped into the same kettle. It is essential to success that the mixture be maintained at a low temperature, below the fusing point of the matte, or the silver will not be removed. The paste plumbiferous charge is then transferred to a second reverberatory furnace, where the removal of all the lead, excepting about 500lb., is effected by reduction with 400lb. of anthracite slack, at a much higher temperature, and by subsequent tapping. The kettle lead is desilverised by zinc, and is then ready for a new charge. The desilverised regulus is run into sand moulds, broken up, and heated to dull redness, with blast from two 1-inch tuyeres. When at a dull red heat the blast is let on, and the mass is kept below the melting point of copper, and is well rabbled for an hour. Mass copper begins to form, and when the fragments no longer have a bright surface the blast is shut off. Eight per cent. of sand is now added for each 12 per cent. of iron originally present,

and the heat raised for copper fusion. The slag formed should be pure black, free from red tinge, and containing less than 1 per cent. of copper; it is skimmed off as fast as it appears, until oxide of copper forms on the surface of the metal bath, when the copper is at once tapped into sand moulds, and afterwards remelted and brought to tough pitch. The slags carrying much lead are reduced by carbon. If the slag should have a red shade, 1 per cent. of raw de-liverised matte will at once clean it of copper. The total loss of lead should not exceed 1 per cent.—W. G. M.

#### *Improvement in the Treatment of Phosphatic Slags.*

Carl Scheibler, Berlin. Eng. Pat. 15,140, November 18, 1884.

WHEN phosphatic slags—and especially those from the Thomas-Gilchrist process—are cooled very slowly, they are found to separate into two layers, the upper one containing the bulk of the phosphoric acid, the lower that of the iron and manganese. It is therefore proposed to run the slags into vessels lined with a non-conducting material, and allow them to cool slowly in bulk until the solidification of the outer surface occurs; the inner fluid portion is then run off, and is found to contain the greater part of the phosphorus as calcium phosphate, which may be treated for manure; the solid crust, containing most of the iron and manganese, is returned to the blast furnace. The longer the time allowed for solidification the more complete will be the separation.—W. G. M.

#### *Improvements in the Manufacture of Phosphatic Salts.*

Sidney Gilchrist Thomas, London. Eng. Pat. 4941, December 12, 1884.

PHOSPHORIC pig iron is run into a basic or neutral lined converter or furnace, into which magnesia to the extent of four or five times the weight of phosphorus calculated to exist in the iron has been already introduced. The usual basic or Thomas Gilchrist or Siemens operation is then carried on till practically all the phosphorus is eliminated from the iron, when the metal and slag are run off separately. The latter contains all the phosphorus as phosphate of magnesia, and is either fused or boiled with an alkali, or else treated with dilute hydrochloric acid for its recovery. The magnesia is also recovered and used over and over again.—A. R. D.

## XI.—FATS, OILS, AND SOAP MANUFACTURE.

#### *The Decomposition of Wool Grease.* Dingl. Poly. Journ. 255 [2], 88.

CERYL cerotate is obtained by Buisine from wool grease by saponifying at 100° C. with alcoholic potash, then distilling off the alcohol forming the barium salt, and then treating with boiling alcohol. The ceryl alcohol, which is difficultly soluble, is obtained from the solution along with homologous crystallisable fatty alcohols. The part of the fat which is the most difficult to saponify contains the largest proportion of cerotic acid.—S. R.

#### *On the Boiling Point and Specific Gravity of Glycerine.* Dingl. Poly. Journ. 255, 208, 1885.

G. TH. GERLACH, in his investigations on glycerine, started with so-called "double-distilled glycerine," which had a specific gravity of 1.23. This glycerine was distilled from a tubulated glass retort until the boiling point remained constant, and the distillation was continued for some time longer. The glycerine remaining in the retort was perfectly pure and clear as water. The corrected boiling point was 290° C. The glycerine boiled very quietly and uniformly, and, on account of its fixed boiling point, can be safely recommended for determining the point 290 on thermometers for high

temperatures. The specific gravity of solutions of glycerine was as follows:—

Percentage of Pure Glycerine.	At 15° C.	At 20° C.
100	1.2653	1.262
90	1.2460	1.246
80	1.2130	1.209
70	1.1850	1.182
60	1.1570	1.155
50	1.1290	1.128
40	1.1020	1.101
30	1.0750	1.074
20	1.0490	1.048
10	1.0245	1.0235
0	1.0000	1.0000

—W. M.

#### *Recovering Oil and Grease from Fibrous Material.* E. S. Wilson and A. B. O'Connor, Camberwell. Eng. Pat. 2621, February 2, 1884.

THIS process has for its object the purification and recovery of oiled and greasy fibres, and extracting valuable products therefrom, by means of chlorinated alkaline leys, hypochlorites of soda or potash. The loose oil is first extracted by hydro-extractors or other suitable means. The waste is then boiled in water or very weak leys, any oil that rises to the surface being skimmed off. The liquor is then drawn off into tanks, that the oil or grease may come to the surface. (If the leys have been used, the addition of acid may be necessary to facilitate the separation.) The waste is then boiled in water containing a small percentage of soap; a solution of chlorinated leys is then added at a strength of 15-20° Tw., and the whole agitated at a temperature of 140-180° F.—J. T.

#### *Hard Soap Making.* C. D. Abel, London. Communicated by Die Fabrik Chemischer Produkte, Berlin. Eng. Pat. 6472, April 17, 1884.

THIS process has for its object the production of a hard soap that shall be practically almost completely freed from the lyes, and that shall contain much less salt than ordinary curd soap, while at the same time a much harder and more neutral product is obtained, containing also less water (from 20 to 25 per cent.) than that obtained in the ordinary way. The soap, separated by salt by the known methods, and before its separation from the lye by complete cooling has taken place, is introduced into a centrifugal machine driven at a high speed, and is subjected, while in a heated condition, to centrifugal action for a comparatively short time (from four to, at most, twenty minutes). By this means the separation of coconut oil soap can be perfectly effected.—J. T.

#### *Apparatus for Cooling Oil in Order to Coagulate Paraffin.* S. M. Henderson, Broxburn. Eng. Pat. 9557, June 30, 1884.

THE apparatus comprises a trough formed with a jacket space through which refrigerated brine or other suitable cooling fluid circulates; and in order to obtain efficient cooling surfaces there are placed within the trough a number of transverse vertical disc casings with thin spaces for the circulation of the cooling fluid. A horizontal rotating shaft passes through the centres of the disc casings, and carries scrapers which detach the paraffin as it congeals on the cooled surfaces; whilst a lower shaft, with agitating arms, breaks up and mixes the congealed paraffin so as to facilitate its discharge along with the oil.—J. T.

#### *Apparatus for Extracting Oleaginous Matters from Bones, etc.* L. Steinmüller and C. Steinmüller, Gummersbach, Germany. Eng. Pat. 11,104, August 9, 1884.

IN this invention the petroleum naphtha or other vapours required for the extraction of fatty matters are forced from the top of the apparatus over the substances to be treated, and pass to the bottom, carrying with them the fat extracted.—J. T.

*Improvements in Materials for Lubricating Metal Moulds.* H. J. Haddan, London. A Communication from C. F. Brush, electrical engineer, of Cleveland, Ohio, U.S.A. Eng. Pat. 3581, Nov. 17, 1884.

IN making lead castings, saponifiable and oxidisable oils have hitherto been used to lubricate the moulds, and the result has been the formation of a hard deposit, partly of lead soap, partly of oxidised oil on the mould-surfaces, which interfered seriously with the perfection of the casting. The inventor claims the use of vaseline, diluted with a hydrocarbon such as kerosene, describing it as a material for lubricating or coating moulds, a non-oxygenous or nonsaponifiable oily substance, and a non-oxygenous or non-saponifiable diluent, both incapable of complete evaporation at the melting point of lead.—W. L. C.

*Improvements in Apparatus for Extracting Fat and Glue from Bones.* G. W. von Nawrocki, Berlin. A Communication from J. Wellstein, of Bamberg, Bavaria. Eng. Pat. 5841, November 25, 1884.

THIS is a description, with figure, of a well-designed and complete arrangement for the treatment of bones in the same extracting vessel: (1) with a solvent such as benzene for the extraction of all fat, the solvent being of course recovered by distillation and used several times in succession; (2) with a weak solution of oxalic or hydrochloric acids, for a greater or less time and under more or less pressure according to the age of the bones; (3) with hot water for the extraction of the glue. A special feature claimed is a perforated coil or rose in the top of the extractor employed in conjunction with an injector below, the effect of which is to draw off the solvent from below and flush the bones with it from above. Details are also given of certain special modes of connecting the extractor with the condenser, the solvent-store and the still in which the solvent is vaporised.—W. L. C.

*The Manufacture of Rosin Soap.* John Murray, London. A Communication from H. J. E. Heunebuth, of France. Eng. Pat. 5154, December 9, 1884.

PRIOR to saponification, powdered rosin is to be treated with sulphurous or sulphuric acids, or with a weak solution of sulphate of alumina. The soap may be used either alone or mixed with a fat soap or with silicate of soda.—W. L. C.

## XII.—PAINTS, VARNISHES, Etc.

*On Iron Paint.* Ding. Polyt. Journ. 255 [1], 48.

THE Dutch Railway Company have tried a series of experiments on the various pigments used for coating iron and their best method of application. They find that red lead is better than any of the oxides of iron used, and that the paint is more satisfactory when the metal has been previously cleaned with hydrochloric acid than when it has only been cleaned by friction. The Cincinnati Southern Railway Company also find that red lead is the best for their iron bridges.—S. R.

*The Preparation of Brilliant-Lac.* Dingl. Polyt. Journ. 255 [1], 48.

TO obtain lac of different colours, coal-tar dyes are dissolved in spirit, the concentrated solution is allowed to stand for a week or two in a dark and cool place and then filtered. The clear solution is then added to the shellac till the required colour is obtained.—S. R.

*Apparatus for Manufacturing White Lead.* J. Kay, Bury. Eng. Pat. 727, January 5, 1884.

THE wicket lead is placed on an endless belt and carried to breaker, or crushing mill, which consists preferably of three pairs of horizontal rollers, placed vertically over each other. The crushed lead is passed through an

inclined revolving screen, the interior of which is studded with pegs to prevent the blue lead from passing through too rapidly. The white lead drops through the perforations of the screen into the hopper of a grinding machine. This consists by preference of three pairs of horizontal rollers placed vertically over each other, each roller sliding horizontally in the contrary direction to its fellow, so as to increase the grinding power and to keep the rollers true.—J. T.

*Improvements in Paints.* F. Wirth, Frankfurt-on-the-Main. Communicated by O. Fischer, Karlsruhe, Germany. Eng. Pat. 2339, February 1, 1884.

THE following mixture is recommended as a body colour to be laid on previous to the oil colour, and which by admixture with further materials is applicable as a substitute for linseed oil: 100 parts of blood, 10 parts of scalded linseed, 190 parts of water, and 10 parts of potassium chromate. Applied as a substitute for linseed oil in mixing colours, this preparation is treated in the proportion of 275 parts with a compound consisting of 75 parts of petroleum, 20 parts of linseed oil, 1 part of pyrosulphite, 1 part of hydrochloric acid, and 3 parts of resin. To combine this compound with the first mixture, 2 parts of soap dissolved in 23 parts of water are added.—D. B.

*White Lead Manufacture.* H. G. Blyth, London. Eng. Pat. 10,375, July 19, 1884.

OXIDE of lead, obtained by the cupellation of impure Spanish lead, or by heating impure carbonates, both mineral and artificial, are employed. When there is much calcareous matter present this crude oxide cannot be advantageously employed. The oxide is placed on a false bottom of porous material in a vessel and treated with solution of lead acetate, an old and well-known process. The solution from beneath the false bottom is run into a second tank and permeated with carbonic acid gas. By a process of upward filtration the liquid overflows from the lower tank, and is pumped back to the upper one. When the bottom part of the lower tank is full of precipitated carbonate it is lowered away from the upper portion, turned over on trunnions and emptied.—J. T.

*Apparatus for the Production of White Lead.* Dingl. Polyt. Journ. 254 [12], 489.

IN order to granulate lead for white lead making, J. C. Martin, of Richmond, England (D.R.P., No. 28,322, of August 31, 1883), lets it fall on a rotating cylinder, from which any adhering lead is removed by scrapers. Graphite or stearite may also be used to lessen the adhesion. The pellets of lead fall from the cylinder A (Fig. 1) upon a movable platform or belt, formed of two endless chains *a*, carrying lathes *m*, keeping the chains at a suitable distance from each other, the whole working over two cylinders *v*. This lead, on falling into the water, is removed on the endless belt *m* and deposited outside the trough. The manufactured white lead is dried in a series of closed cylinders A (Fig. 2), each of which contains a worm *s* formed of copper bands to impel the white lead forwards. The supply funnel *t* leads to a cylindrical chamber, in which a shaft *o* revolves slowly, carrying arms covered with leather which conducts the supply of white lead gradually to the drying chambers. The cylindrical chamber *k* represents an enlarged continuation of the cylinders A, and contains a paddle-wheel *r* fixed to the shaft *o*. The paddles *α* are so placed that by revolving in the direction of the arrow the white lead is removed from the chamber *k* into the end of the second trough. When the white lead arrives at the end of the first cylinder, it falls into the chamber *k* through the opening *x* in the sides of the wheel *r* and through the spaces between the paddles *α*, so that by the continued motion of the paddle-wheel the white lead is carried up on the inner circumference of the chamber *k* until it falls through the opening *ν* into the next trough A. Here the white lead receives motion in an opposite direction by the worm *s*, and finally leaves the apparatus at the opening N of the last trough. The hot

air used for drying enters through a conduit above, on one side of the cylinder, and escapes on the other side through a pipe *z*. The washing apparatus, for separating white lead from unattacked metal, of H. Kirberg, of Hilden, near Düsseldorf (D.R.P., No. 28,528, of January 9, 1884), claims to be more efficient and less liable to get out of order than the one invented by Horn.

beaters *f* screwed on to the beams *e* (Fig. 4), effect a thorough agitation and thereby a rapid separation of the mass of oxide into its constituents. The perforated tray-shaped discharging scoop *g*, which takes up the particles of lead freed from oxide from the bottom of the vat and throws them into the funnel *h*, is movable on its upper portion round a peg attached to an arm *i*,

Fig. 1.

Fig. 2.

Fig. 3.

As will be seen by reference to Fig. 4, the copper vat *b* completely closed with a wooden cover and fastened to the cast-iron supports *a*, is fed with the mass of oxide to be operated on, and also with the necessary washing liquid through the funnels *C* (Fig. 3) fixed to the vat. The two reels *d*, turning in opposite directions by means of toothed wheels driven by pulleys and provided with

whereby it can be set forwards or backwards according to the required amount of discharge by means of a screw arranged underneath. In order to effect a slow or quick washing of hard, or in the other case of soft, oxide the coupling *l* is opened, by which the cross-piece *m* running loose on the axle can be turned a little, whilst the second cross-piece remains fixed, and in this way the beams *e* and

the surfaces of the beaters are brought to an inclination with the axis of the apparatus, whereby the rapidity of the motion of the mass towards the place of exit is regulated. After the required displacement of the beams *c* (Fig. 5), the coupling *l* is again closed, and by screwing tight is ensured against becoming loose again. The water, charged with lead oxide, flows through the sieve

Fig. 4.

osituated at the surface of the liquid into the long box closed with a lid and through the trough *q* into the settling vat. The protecting screen *r* which, hanging from the sieve *o* and leaving an opening underneath, and is easy to remove for cleaning, prevents the entrance of small metallic particles of lead into the sieve, whilst the direction of motion of the mass of oxide, and therewith also of any accompanying particles of metal, tends downwards on the side walls of the apparatus.—G. H. B.

### XIII.—TANNING, LEATHER, GLUES, SIZES, AND RESINS.

*Improvement in Tanning.* Frank Werth. Eng. Pat. 1857, January 21, 1884.

THIS covers the use of dried peat moss made into bricks or mixed with vegetable tanning materials rich in tannin, and also with mineral tanning substances, such as alum, salt, and chromate of potash.—H. R. P.

*Improvements in Apparatus for Tanning Hides and Skins.* Ambrose Myall, London. Eng. Pat. 3174, February 12, 1884.

TWO or more laticed tanning drums of the ordinary description are placed in a circular vat provided with a vertical shaft in the centre, by means of which the drums are made to rotate round the vat, at the same time turning on their axes with a rolling motion. The vat is supplied with liquor by a centrifugal pump, from a series of tanks in which it is filtered and settled. The patentee also claims the ordinary form of tanning drum which has been in use in English and American tanneries for more than 20 years.—H. R. P.

*Improvements in Machines for the Manufacture of Leather.* Ambrose Myall, London. Eng. Pat. 3374, February 15, 1884.

THE subject of this patent is a machine identical in construction with the Priestman striking machine generally used in finishing off; the use of serrated blades for fleshing and unhairing; and the drum is to be covered with pumice, emery paper, or cloth, for various other operations, such as ruffing, whitening, and polishing.—H. R. P.

*Improvements in Waterproofing Leather.* Wm. J. Gale. Eng. Pat. 4826, March 13, 1884.

THE leather, after washing with warm water, or with weak solution of soda or other alkali, is exposed to the fumes of ammoniacal gas, and then slowly dried in a closed chamber.—H. R. P.

*Improvements in the Treatment of Leather.* James Paterson. Eng. Pat. 6756, April 24, 1884.

LEATHER intended for belts, hose pipes, etc., either carried or rough dried, is soaked in a solution of wood-resin and gum thus (frankincense), melted together, dissolved by heat in linseed oil, and afterwards mixed with petroleum, benzolene, or bisulphide of carbon, and a

Fig. 5.

small quantity of India-rubber solution. When thoroughly saturated, the leather is washed in a bath of petroleum-benzolene, and dried on racks or otherwise. The tendency of the leather to stretch is said to be materially lessened.—H. R. P.

*Improvements in the Process for Tanning Tawed Leather.* Caesar Kaestner, Magdeburg. Eng. Pat. 11,442, August 19, 1884.

ALUMED leather is tanned with a solution of tannin in alcohol instead of water, by which the leather is completely tanned in eight days. Tannin, catechu, and picric acid are mentioned as suitable materials.—H. R. P.

### XIV.—AGRICULTURE, MANURES, Etc.

*On the Preparation of Phosphates.* Dingl. Polyt. Journ. 255 [1], 35.

DREYFUS obtains phosphoric acid from mineral phosphates by treating them with sulphuric acid in leaden vessels. The gypsum formed is removed by a filter-press, and the solution of phosphoric acid concentrated by causing a flame to play upon the surface of the liquid, which is placed in a leaden pan over an open fire. The pan rests on a bed of sand, and is surrounded by a wall of stone. In an oven 5 or 6 metres long, and 1·5 wide, 8000 kilos. of phosphoric acid can be concentrated. A less advantageous method is to concentrate the solution in wooden vessels lined with lead, by means of superheated steam under 3 or 4 atmospheres. The precipitate consists mainly of gypsum, undecomposed oxides of iron and alumina, and from 2 to 3 per cent. of combined phosphoric acid. It is used as a manure under the name of *phosphate-gypsum*. The phosphoric acid can be mixed with powdered phosphates to form super-phosphates containing 43 to 44 per cent. of soluble phosphoric acid, or can be used for the preparation of precipitated phosphate of lime. Adair and Thomson (D.R.P., Class 16, No. 28,739, August 12, 1883) obtain the phosphoric acid out of slags and minerals, by first reducing to a fine powder, then roasting if carbonic acid or calcium phosphate is present, and finally decomposing with strong caustic soda in the proportion of three equivalents of soda to one of phosphoric acid. The mixture is strongly heated in iron vessels, and the solution of phosphate of soda filtered or decanted from the precipitate. The solution when concentrated can be purified from silica, alumina, manganese or iron, by passing through it a current of air and carbonic acid. The precipitate is separated, and calcium phosphate thrown down from the solution by the addition of milk of lime. If a basic slag or iron ores containing phosphorus is being used, a mixture of potassium and sodium carbonate solutions is employed instead of the caustic alkali. Caustic ammonia or ammonium car-

bonate solution can be employed in the same way in closed vessels. The ammonium phosphate can be crystallised from the solution, or calcium phosphate can be prepared as previously by precipitation with milk of lime.—S. R.

*On the Preservation of Frozen Potatoes.* Dingl. Polyt. Journ. 255 [1], 45.

FITTEOGEN has examined frost-damaged potatoes which had been stored in silos, and finds that they lose their value as a food stuff very rapidly. He analysed the ensilage after 50, 76, and 140 days, and found that the loss of fat increased from 57.1 per cent. after 50 days, to 87.0 per cent. after 140 days. A corresponding loss in the amount of starches and albuminoid substances was also noticed. This method of preservation is not to be recommended.—S. R.

*Value of Cockchafers as a Manure.* Dingl. Polyt. Journ. 255 [1], 46.

F. A. WOLF kills the chafers by enclosing them in a vessel with carbon-bisulphide. After ten or twenty minutes they are dead, and can be then heated to 60° in a kiln for five hours; they lose in this way about 65 per cent. of their weight, but when dried can be kept for any length of time. The product contains 12 per cent. of nitrogen, 1.2 per cent. of phosphoric acid, and 1.2 per cent. of potassium. The organic matter consists of 38 per cent. of albuminoids, and 10 per cent. of fats.—S. R.

*On the Employment of Artificial Manure in Potato Culture.* S. Guradze. Biedermann's Cent.-Blatt. 1883, 6, 377.

The author made experiments with Chili saltpetre, superphosphate and patent "potash-magnesia." The tabulated results are as follow:—

Field.	MANURE PER ACRE.				Cost of Manure.	Yield per Acre, ctr.	Starch %.	Starch per Acre, kg.
	Stable Manure, ctr.	Superphosphate (20% P.), kg.	Chili Saltpetre (16% N.), kg.	Patent Potash-Magnesia, kg.				
I.	90	—	—	—	—	63.0	14.0	411
	90	30	25	—	12.30	76.2	15.4	587
II.	90	—	—	—	—	72.2	15.1	545
	90	—	—	25	3.20	81.7	15.8	669
	90	25	—	25	7.20	81.3	16.0	671
	90	25	25	32	11.90	88.1	16.4	727
III.	—	37.5	37.5	—	17.25	93.0	13.9	616
	—	—	—	—	—	86.0	13.5	581
IV.	90	—	—	—	—	92.0	14.7	676
	90	25	—	—	1.90	104.6	14.9	779
	90	—	25	—	7.50	119.0	15.4	898
	90	25	25	—	11.50	128.2	15.6	999
V.	80	—	—	—	—	82.0	16.6	681
	80	35	—	—	5.60	85.2	15.4	656
	80	35	35	—	16.10	86.0	16.0	688
	80	35	35	50	22.50	96.3	15.5	716

The soil of Nos. I. and II. fields was a loamy sand; that of No. III., loam; No. IV., loamy sand to sandy loam, and pure loam of the muschelkalk formation; and No. V., warm loamy sand.—E. G. C.

*On the Manurial Value of the Deposit from Urban Refuse-Water.* M. Fleischerem. Biedermann's Cent. Blatt. 1883, 6, 426.

IN Bremen, the waste-water from houses and manufactories, together with large quantities of urine, is conducted by channels into a river with a sluggish current. The deposit formed in the river bed has been examined by the author, who finds it to possess an acid reaction, and to contain hydrated ferrous oxide. On ignition in a platinum dish, sulphurous acid is given off. One thousand parts of this material contain:—

	Dry.	With 45 per cent. water.
Potash	6.3	3.5
Lime	17.2	9.5
Phosphoric acid	8.0	4.1
Total nitrogen	11.6	6.1

By exposure to the atmosphere and consequent loss of water, the fixed constituents could be brought to from 50-60 per cent., and 25 centners would then be worth 18 marks, and contain 4.4kg. potash, 12kg. lime, 5.5kg. phosphoric acid, and 7.0kg. nitrogen. The material must be exposed to the air for some time before being applied to the soil, because of its richness in sulphur compounds. The sulphuric acid, resulting from the oxidation of the metallic sulphides, would be advantageously neutralised by an admixture of calcareous matter. Another example of deposit from a pond, with which the refuse matter of a portion of the town had been conducted for a long period, furnished the following figures:—

	As collected.	Dried at 100 degrees.
Water	889.7	—
Combustible matter	27.2	251.0
Nitrogen therein	1.46	13.2
Insoluble in HCl	52.25	498.8
Potash	0.98	8.9
Soda	0.94	3.1
Lime	1.91	17.3
Magnesia	1.35	12.2
Ferrie and aluminic oxides	18.25	165.5
Phosphoric acid	0.52	4.7
Sulphuric acid	3.65	33.1

This sample, as collected, had an acid reaction, and

evolved much sulphuretted hydrogen on the addition of HCl. With a proportion of 45 per cent. of water, 25 centners of this material would represent a value of about 19.4 marks.—E. G. C.

*On the Employment of Basic Phosphate of Lime as an Addition to Fodder.* Dr. Cohn. Biedermann's Cent.-Blatt. 1883, 6, 428.

THE author, after referring to the writings of Lehmann, Göhren, and Schieweck, who state that calves, bullocks, sheep, and swine assimilate calcic basic phosphate, recommends this compound as being a wholesome addition to cattle food. To lambs and young pigs 8-12 grm. per head and day should be given, to calves and foals 12-20 grm., and to cows and bullocks 20-25 grm.

—E. G. C.

*Remarkable Influence of Manuring on the Composition of Potatoes.* Professor M. Märcker, Graeger and Vibraus-Calvörde. Biedermann's Cent.-Blatt. 1883, 6, 365.

THE experiments were carried out on a good soil of sandy loam, which in the previous year had yielded barley and clover. The manure used contained 20lb. of soluble phosphoric acid per acre, together with varying quantities of Chili saltpetre. Certain plots were left unmanured. The yield of potatoes was greater on the manured plots than on the unmanured, but it was found that manuring with considerable quantities of Chili saltpetre had had the effect of considerably diminishing the percentages of dry substance and starch (the latter by as much as 6 per cent.). The albumen and other nitrogenous constituents were, however, augmented.—E. G. C.

*The Manuring of Beet-Roots.* Dr. Holdefleiss. Biedermann's Cent.-Blatt. 1883, 6, 380.

As the result of his experiments, the author concludes that a moderate quantity only of stable manure, together with Chili saltpetre, should be used; also that manure too rich in nitrogen has a pernicious influence; and finally, that in the absence of stable manure, the addition of Chili saltpetre and superphosphate simultaneously is to be recommended.—E. G. C.

*A New Material for the Manufacture of Peat Manure and on the value of this kind of Manure.* M. Fleischer, C. Spierlog, and others. Biedermann's Cent.-Blatt. 1883, 6, 368.

HITHERTO moss-peat from the North German moors has been chiefly used; the principal characteristics of this peat are its affinity for moisture, its elasticity and softness, even when dried, its property of absorbing ammonia and carbonate of ammonia from refuse animal matters, and its high proportion of nitrogen as compared with other similar materials. It is now proposed to employ a fibrous peat from Schleswig and Württemberg, consisting chiefly of *phragmites communis*. One hundred parts of the air-dried Württemberg peat (containing 20 per cent. of water) were found to absorb and hold 933 parts of water, while 100 parts of the Schleswig peat took up and held 630 parts of water; 1000 parts of Württemberg peat absorbed 16.5 parts of nitrogen in the form of ammonia, and 1000 parts of Schleswig peat absorbed 13.0 parts; 1000 parts of the ordinary North German moss-peat absorbed 17 parts of ammoniacal nitrogen. A comparison of the three kinds of peat, as regards their constituents, yielded the following results in 1000 parts of completely dried material:—

	Württemberg fibrous peat.	Schleswig fibrous peat.	North-West German moss peat.
Nitrogen ... about	22 parts.	29 parts	9 parts.
Phosphoric acid...	0.6	0.6	0.4
Lime .....	17.2	31.0	2.0

It is evident from these figures that both the Württemberg and Schleswig peats are considerably richer in nutritive constituents than the moss-peat. Experiments made by several observers as to the efficacy of manures, consisting of admixtures of peat with other substances, such as Chili saltpetre, bone-meal, stable manure, etc., have yielded decidedly satisfactory results.—E. G. C.

*The Behaviour of Legumin with Solutions of Common Salt.* H. Ritthausen. Biedermann's Cent.-Blatt. 1883, 6, 398.

TH. WEYL discovered that leguminous seeds contain proteid bodies soluble in a solution of salt. The author made some legumin preparations by extraction with aqueous potash and precipitation with acetic acid, and found them to be for the most part insoluble in salt water. The salt water solutions, however, gave when highly diluted considerable precipitates, which after washing with alcohol and drying over sulphuric acid, formed white, shining, brittle masses. Legumin from pease furnished 20.6-26.2 per cent. of proteid matter soluble in salt water; that from broad beans, 18.8 and 28.8 per cent; legumin from vetches, 23 per cent.; and that from chick-pease (*Lathyrus*), 24.8 per cent. The composition of the soluble matter (calculated on the material free from mineral matter) was as follows:—

	From the legumin of pease.	From the legumin of broad beans.
C.....	51.62	50.33
H.....	6.96	6.95
N.....	18.26	17.91
S.....	0.33	0.27
O.....	22.83	23.91

The compounds of tannic acid with albuminoid bodies are completely insoluble in salt water, and as the occurrence of tannic acid in the shells of beans, pease, etc., is very frequent, it is necessary in preparing the proteid substance from seeds to first remove the shells. The incomplete solution in salt water of the legumin present in seeds proves that the latter is a mixture of several proteid bodies. The constituent of pease, soluble in salt water, does not differ essentially in composition from the body extracted by the aid of aqueous potash, and is very similar to the conglutin of lupines, although not identical with it, as the following figures will show:—

		Conglutin.
C.....	51.62	50.33
H.....	6.96	7.03
N.....	18.26	18.67
S.....	0.33	1.07
O.....	22.83	23.07

—E. G. C.

*On the Influence of the Electric Light on the Development of Plants.* P. P. Dehérain. Biedermann's Cent.-Blatt. 1883, 6, 408.

THE author's experiments were made with plants continuously exposed for many days and nights to the rays of the electric light, which in some cases were allowed to fall directly upon the plants and in others were caused to pass through the sides of transparent glass globes. Experiments in this direction had been previously made by Siemens, but not for such extended periods. The effects of the naked rays noted by Dehérain were very curious; some of the plants lost their leaves, some became spotted, weak and unhealthy, others turned black, while in the case of some elder shrubs, leaves directly exposed to the electric rays were blackened, although the more protected leaves retained their green colour. The outlines of the upper leaves were found in many instances depicted on those underneath with the distinctness of photography. The influence on vegetation of electric rays which had passed through transparent glass globes was not so prejudicial, although complete development was greatly interfered with. The following conclusions were arrived at by the author: (1) the electric light contains rays which are injurious to vegetation; (2) the greater part of these rays are kept back by transparent glass; (3) the electric light contains, on the other hand, sufficient rays useful to vegetation to maintain the life of plants entirely under its influence for 2½ months; (4) this amount of useful rays is, however, insufficient to bring on young germinating plants or to bring full-grown plants to maturity.—E. G. C.

*Defects in the Present Method of Butter-making.* Otto Biedermann's Cent.-Blatt. 1883, 6, 417.

THE author calls attention to several imperfections in the production and working of milk for butter-making. The

animals yielding the milk should be rationally fed; for example, the food given to them must not contain a disproportionately large amount of any one ingredient, to the exclusion of others. Then, again, the milk yielded by old milk-kine is slightly bitter and furnishes bitter butter; too much of such milk should therefore be avoided. Particular care must be taken that the air of the cowhouse be as pure and sweet as possible, and that no milk be allowed to remain there for a longer time than is absolutely necessary. The churn also should be in an airy and well-ventilated position, and all vessels used must be cleansed with the most scrupulous care. Neglect of any of these points involves a risk of the production of butter unsatisfactory in quality and in taste.—E. G. C.

*Improvements in the Treatment with Sanitary Objects of Human Excreta and other Putrescible Matter; and in Apparatus and Means employed in the Conversion of the same for Manurial Purposes.* Richard Nicholls, Hendon. Eng. Pat. 94, January 1, 1884.

THE fœcal matter is to be received in a vessel provided a removable air-tight hollow cover, charged with soot or other carbonaceous material, which falls upon and deodorises the excreta when the cover is re-placed by a person using the apparatus. The receptacle is constructed so as to be readily portable, and is adapted for being heated over a stove, with the object of partially or wholly driving off the moisture from the contents, which, after this firing process, are of high value for manurial purposes.—E. G. C.

*Treatment and Disposal of Sewage.* Fritz Hille, Chiswick. Eng. Pat. 1279, January 11, 1884.

THIS invention consists essentially in treating sewage with magnesium, calcium, ferric, or other chloride, or with calcium oxychloride, or with alum followed by lime-water; the effluent water so produced being sufficiently purified for discharge into rivers or the sea. Where particularly strong and offensive sewage has to be dealt with, a small quantity of diluted carbolic acid may be added with advantage. The sewage deposit may be dried, crushed, and compounded with kainite, or with phosphate of lime, and profitably disposed of as artificial manure.—E. G. C.

*Treatment of Sewage.* J. B. Mills, Southampton Buildings, London, W.C. Communicated by Jean Marie Guénantin, Rue d'Hautville, Paris. Eng. Pat. 2568, February 1, 1884.

A SPECIAL re-agent is prepared by dissolving 4 parts bauxite in 50 parts hydrochloric acid by the aid of a jet of steam, and adding 30 parts phosphate of lime. This re-agent is mixed with the solid or sludge matters of excreta or sewage in closed vessels, and the mixture is dried, filter-pressed, and ground, forming a manure containing 3.4 per cent. nitrogen, and 8.12 per cent. assimilable phosphoric acid. The liquid portion of the matter to be dealt with is heated, mixed with lime, and the ammonia distilled off, all in a special arrangement of apparatus claimed by the inventor. The heated liquor, deprived of ammonia, is cooled by traversing a circulatory apparatus containing fresh liquor from which the ammonia has to be extracted. Various detailed processes are claimed, and a drawing is given of a complete arrangement of vats, precipitating tanks, heaters, stills, etc., for dealing with the excreta of a town.—J. M. H. M.

*Dissolving Leather for use as Manure.* By William Martin, Wadebridge, Cornwall. Eng. Pat. 3493, February 18, 1884.

LEATHER chips or shavings are mixed with potash, soda, lime, or other alkali, and heated by steam at 20 to 40 lb. pressure, for 20 to 60 minutes, then dried and ground.—J. M. H. M.

*Recovering Nitrogenous Matters from Certain Deposits.* J. C. W. Stanley, 41, Barnsdale Road, Middlesex. Eng. Pat. 1843, February 21, 1884.

RIVER mud collected in the vicinity of sewage outfalls contains a considerable proportion of nitrogen. Mud

dredged from the still waters of the London Docks contains, according to the inventor, 47 per cent. N. The inventor proposes to dredge up river mud, dry it, and submit it to destructive distillation in order to recover this nitrogen in the form of ammonia.—J. M. H. M.

*Making Sewage Refuse into Manure.* F. G. Redman and J. Butt, Peterborough. Eng. Pat. 3996, February 27, 1884.

IN the process patented for the conversion of sewage into manure, solid sewage refuse is treated with lime and sulphuric acid, employing for a ton of refuse 5 to 10 cwt. or even a ton of the former and a carboy (about 60 lb.) of the latter; several superincumbent layers are constructed in the order—sewage, lime, sprinklings of acid, finishing with a final covering of sewage. The resulting mass is mixed, for every ton of sewage employed, with 14 lb. ammonium sulphate, 14 lb. to 28 lb. each of potash and kainite, and, if desired, 14 lb. sodium nitrate; these quantities are, however, regulated according to the quality of manure required, and the introduction of the last ingredient is quite optional.—D. A. L.

*Mill for Grinding Phosphates and other Materials.* Isaac Brown, India Buildings, Edinburgh. Eng. Pat. 9457, June 26, 1884.

A HOLLOW drum is driven at a high speed and the material to be ground is fed into it through the trunnions. In contact with the inside surface of the rim of this drum are small rollers which effect the grinding. The rim may be perforated or reticulated. A drawing is annexed to the specification.—J. M. H. M.

*An Improved Method of Purifying or Disinfecting Sewage, and of Collecting the Ammonia, etc., contained therein, for Manurial Purposes.* S. D. Cox, New Charlton. Eng. Pat. 12,345, September 12, 1884.

ACCORDING to this invention, sewage is conducted from the sewers by means of pumps into a tank provided with several rows of plates or walls so arranged as to break or interrupt the flow of the sewage through, and to cause the greater part of the insoluble or heavy matter to become deposited at the bottom of the tank. The liquid portion is then allowed to flow over into a second tank containing a number of strainers or frames filled with peat or other suitable material. These strainers permit the liquid sewage to pass through them very rapidly, becoming, in its course, so purified that it passes from the second into the third tank in a comparatively clear condition. The third tank possesses a perforated false-bottom, on which is a layer or filter-bed of coarse peat-charcoal covered by another layer or bed of powdered or granular charcoal. These beds are about 6 in. thick and provided with a perforated iron cover. After passing through these filter-beds the liquid will be bright and clear, and may be allowed to flow into a river or elsewhere.—E. G. C.

## XV.—SUGAR, GUMS, STARCHES, Etc.

*On the Formation of Sugar in Roots.* Dingl. Polyt. Journ. 255 [1], 46.

GIRARD, in the *Comptes Rendus*, 1884, 99,808, has shown that saccharose is formed in the leaves of sugar-beets by the action of light and then passes into the roots. The proportion of saccharose to glucose is always much greater in the daytime than at night, sometimes being as great as four times as much. The formation of saccharose takes place in the leaves even when severed from the plant.—S. R.

*Working up Diffusion Residues from Sugar.* Dingl. Polyt. Journ. 255 [3], 127.

IN order to remove water as much as possible from the colloid matter in the cuttings, M. Maerker, of Hailo

(Germ. Pat. No. 29,640, March 2, 1884), adds lime. Either caustic lime, slack or quick, powdered lime, or milk of lime may be used, also carbonate of lime. The addition of lime may take place without warming or the mixture may be warmed. It is stated that pressed cuttings containing 10.9 per cent. dry matter, when treated with 5 per cent. of lime were, by a second pressing equal to a few atmospheres, converted into a mass containing 25 to 30 per cent. of dry matter. The same pressure applied to cuttings not treated with lime gave only 15.6 per cent. dry matter. The addition of lime can take place in the presses or in the diffusers. No considerable removal of nutritious matter from the cuttings is observed, and owing to the small amount of lime added the dry matter contains but a small percentage more lime, which is not injurious and indeed rather beneficial as regards keeping properties and action of the cuttings as food for cattle; also the press-waters are removed in a much purer condition. Besides, by means of lime and carbonated and caustic alkalis, the introduction of osmose processes causes a large proportion of the water, which is tenaciously retained by diffusion residues, to become removable, and for this purpose common salt or other easily soluble salts of alkalis and alkaline earths may be employed. This process is applicable to the removal of water from other sugar residues, also from the residues of distilleries, starch manufactories and breweries, which are used for feeding cattle. Further, it may be employed for removing water from very damp materials used for fuels such as tanner's waste and especially turf.—H. A. R.

#### New Apparatus for the Manufacture of Sugar.

Dingl. Polyt. Journ. 255, 202.

For estimating the soil on beets and potatoes, P. Reus (Germ. Pat. 25,755, April 3, 1883) employs (Figs. 1 and 2) a trough *d*, which can be raised and lowered on the cast-iron stand *a* by means of the lever *f*. The beam *b* carries at one end a weight pan, and at the other a washing drum, which dips into the trough *d*. The roots are placed in the drum, their weight determined, then the

Fig. 1

trough is raised, and by turning the handle of the drum the roots are washed. After lowering the trough and letting the water drain off they are weighed again, and the loss in weight corresponds to the amount of adhering soil.

P. Suckow & Co., Breslau (Germ. Pat. 25,207, February 27, 1883), have devised a mill for preparing beets for analysis (Figs. 3 and 4). The roughly cut roots are thrown into the box *a*. Motion is imparted to the mill-stone *d* by the shaft *e* and the bevelled wheels *f*. The stone rotates in the cylindrical part of the case *h*, which is provided with teeth on the inside. On this two spur

wheels work, and effect a complete grinding and crushing of the beet chips. When the chips are properly prepared they fall into the space *r*, in which they are reduced to the desired thin pulp, which is removed at *i* by a scraper. The space *r* can be adjusted by turning the screw *b*. A scraper *R* rotates with the shaft *n*.

O. Licht, Sudenburg (Germ. Pat. 25,062, March 13, 1883), in order to facilitate the solution of sulphurous or carbonic acid during saturation of the beet juice, attaches movable sieves *a* of metal or wickerwork to the inside of

the vessel at *b* (Fig. 5), so that by means of the rods *d* they can be fixed in such positions as to give the desired resistance.

The juice filter of A. Vibraus (Germ. Pat. 27,362, June 21, 1883) is made of perforated sheet iron, and covered with a suitable filter cloth, so that the liquid contained in

the vessel *a* (Fig. 6) passes from the out to the inside, and flows off by the pipe *d*, which can be readily removed by loosening the intermediate piece *c* when it is necessary to clean the filter.

In the juice filter of O. Licht (Germ. Pat. 27,364,

October 24, 1883), the liquid enters by the funnel-shaped pipe B (Fig. 7), falls on the distributor C, and thus on to the filtering material, which rests on the false bottom *s*. The filtrate passes through the pipes *a*, *b*, and *d* into the

receiver *L*. The pipe *c* serves to discharge completely the liquid from the filtering chamber *F*, while the pipe *e* prevents the vessel from becoming empty during the

operation. The pipes *f*, *g*, *h*, *i*, *k*, connected with the common air pipe *m*, serve to regulate the suction height of the column of liquid flowing away, according to the

resistance offered by the filter to the passage of the juice. The pipe *n*, used for washing the sweet out of the filtering medium, opens into the overflow pipe *O*, which is connected with the vessel *M*. The filter is charged with juice by the pipe *B*, and the cocks *c* and *f* are opened; at first it works simply by the pressure corresponding to

the difference in the level between the liquid in *F* and *d*, when the rate of flow diminishes owing to the filter becoming choked, the cock *f* is shut and *g* opened, whereby the outflow increases again. This is repeated from time to time with the other cocks. By increasing the length

of the suction pipe *d* almost any resistance in the filter may be overcome; when the filter is exhausted the cock *c* is opened, and the last portion of the juice allowed to flow out.

The bag filter of Th. Otto (Germ. Pat. 29,026, January 22, 1884) consists, as will be seen from Fig. 8, of a cylindrical vessel *a*, with two perforated plates *b* and *c*,

in which are fixed the pipes *n*. Other pipes, perforated at the lower end, in which filter bags are hung, are placed inside the first pipes. The bags are filled with coarse charcoal or sand, and the juice contained in the space *x* flows through the bags and collects in *m*, and is conducted away by the pipe *re*. The apparatus is heated by waste steam, which enters at *o* and surrounds the pipes.

In order to prevent the steam from passing from the montejus into the filter presses, E. Schulze (Germ. Pat. 29,044, March 30, 1884) employs a vessel which communicates with the filter presses by the pipe *C* (Fig. 9), and contains a float *a*, to which the valve *f* is attached. The apparatus is started by raising the float by means

235

of the handle, when the vessel containing it becomes filled with the liquid to be filtered; after all the liquid has passed the float falls, shutting the valve *f'* and preventing the steam from entering the presses, and opening the valve *g*, by which the steam escapes.

Figs. 10 and 11 show an apparatus (G. Bokelberg, Germ. Pat. 28,661, March 11, 1884) for drying beet roots

as they come from the washing machine. They are discharged into the drying apparatus, and fall on the sieve surfaces *s*, and finally discharge themselves at *C* into a wagon. The water adhering to the roots passes through the sieves and collects on the inclined plates *r*, and flows away by the pipes *r*. A blast of warm air passing up the apparatus completes the drying of the roots. The small doors *c* are to be used in the event of any

stoppage occurring in the drying apparatus, or for cleaning the shelves.

F. Rothe's *Söhne*, Bernburg (Germ. Pat. 29,077, April 11, 1884). 'In order to increase the total section of the heating space in the vacuum pan, divide it into two parts by the divisional plate *a* (Figs. 12 and 13). The lower space *C* contains a number of horizontal pipes *d*, which open into the spaces *E* and *F*, and are connected with the upper part *B* by means of the elbow *g*. By using

either the pipes  $n$  or the elbow  $g$ , which communicate between B and E, circulation of the liquid will take place in the direction indicated by the arrows. Steam is admitted into the space C, which is completely shut off from the liquid, and passes round the pipes  $d$ , which are full of the liquid, and along the lower side of the divisional plate  $a$ . It also heats the tube plates of the

chamber C, and communicates heat to the solution in the spaces E and F.

The circulation of the liquid in this apparatus greatly assists the evaporation.

Fig. 14 represents another arrangement to keep the liquid in continual motion during evaporation in a vacuum pan, and is the patent of J. P. Liebe, Dresden (Germ. Pat. 27,614, October 19, 1883). A knee pipe  $a$  is fixed to the bottom on the pan, having a valve  $c$  to which the T-pipe  $i$  is attached. The pipe  $c$ , closed at the top,

surrounds the tube  $k$ , one end of which  $q$  opens into the vacuum pan, while the other terminates as shown in the T-piece  $i$ . When the stop-cock  $p$  is opened, the air pump is started, and the solution to be evaporated is allowed to enter by  $n$  until it reaches  $q$ . The cocks  $n$  and  $p$  are

now shut, and the vacuum destroyed by opening the cock *d*. By shutting *d* and again opening *p*, the solution standing over *f* is drawn through *h* in the vacuum pan, then another portion of the liquid passes through the valve *C* into *i*, from which it is drawn again through *h* into the pan. The liquid is thus caused to circulate intermittently. If it is desired to make a continual discharge at *g*, the arrangement of pipes *a* and *h* are placed lower, as indicated by the dotted lines. By partially opening the cock *n* a continuous feed will be maintained. —W. M.

*On the Production and Examination of Starch.* Dingl. Polyt. Journ. 255, 209.

IN the *Zeitschrift für Spiritus-industrie*, p. 762, 1884, O. Saare gives the results obtained in a factory where the process was conducted without grinding, the potatoes being passed through a rasping machine. Two experiments were made with 4800kg. washed potatoes (I. Seed; II. Zwiebel), and these quantities were worked into starch giving:—

	I.		II.	
	Kg.	Per cent.	Kg.	Per cent.
Wet pulp .....	1786	37.2	2,381	17.5
Dry pulp .....	—	4.6	—	5.7
Green starch .....	1,213	25.6	1,233	25.7
Dry starch .....	—	13.3	—	13.0
100kg. potatoes gave starch in the pulp	2.96	—	4.05	—

The following figures show a comparison between the yield obtained when only a rasping machine is used, and when, in addition to this, grinding is employed, from 100k. of starch worked:—

STARCH.	SEED.		ZWIEBEL.	
	Without Grinding.	With Grinding.	Without Grinding.	With Grinding.
Obtained in form of green starch .....	81.8	87.4	76.3	85.5
Lost in the pulp .....	18.2	12.6	23.7	14.5

This table shows the advantage attending the employment of grinding for increasing the yield of starch. It should be noted, however, that the factory with the grinding plant employed a rasp cutter, while in the other case a rasping machine was used, which does not distinguish the material so finely.

According to L. Bondonneau, errors are made in the estimation of the total solids in starch, when damp starch is heated to quickly over 60° C. When the starch contains acids, sugar is formed during the drying. He recommends the starch to be spread in a very thin layer, heated slowly to about 60° C. for three hours, then kept at 100° C. for one hour. If the starch be acid he adds a few drops of ammonia and water, and proceeds as before.

On the other hand, Saare (*Zeitschr. für Spiritus-industrie*, 595, 1884) heats 10gram. starch to 40° or 50° for one hour, and then keeps it at 120° for five or six hours. Numerous experiments have shown that for commercial analyses five or six hours' drying at 120° suffice to drive off all the water. He also says that the error caused by the conversion of starch into glucose, when starch having an acid reaction is dried, can be safely neglected. The amount produced when the starch contains 1 per cent. of sulphuric acid does not influence the estimation of the water, consequently there is no need to add ammonia to acid starch.

S. Schuberth (*Monatshefte für Chemie*, p. 472, 1884) has investigated the behaviour of starch granules on being heated, and concludes that changes in form and structure, especially the lamination, are not solely determined by the amount of moisture in the air-dried granules, but depend on the different physical and chemical properties of each layer. The effect of heat is simply to make these differences more prominent. The starch granule, under the influence of high temperature, is altered in such a

manner that the layers, rich in granulose\*, are at once converted into soluble starch and dextrin, while the principal portion of the layers, rich in cellulose only, undergo this transformation after a time. When starch which has been heated is treated with water of the ordinary temperature, the soluble starch and dextrin are removed, and an organised residuum is left, which resembles the form and structure of the original granule, and contains small quantities of unchanged granulose. This can be further removed by extracting with water, and it appears to be so altered that it can be easily subjected to chemical changes. The granules give up the greater portion of the granulose to the water, thereby losing in mass but not in volume, retain their structure, and consist chiefly of cellulose.

Granules extracted in this way become coloured blue, or, at least, bluish violet, on the addition of sulphuric acid and iodine, and the individual layers swell up and separate from one another. When the granules are heated more strongly with a drop of water, on the object glass, a deep blue colouration ensues. The residue is not a uniform body, but contains, in addition to cellulose and granulose, a transformation product of starch similar to dextrin which reduces Fehling's solution, is coloured red by iodine, and undergoes decomposition on treatment with water. At present it cannot be decided whether this body is erythro-dextrin or not. If a large quantity of the granules be triturated with pounded glass, the substance yielding the red colour cannot be removed by repeated treatment with cold water, which presumably would not produce decomposition or alteration; on the contrary, by the addition of iodine the residue becomes more intensely coloured, while the rotatory power remains practically unaltered. —W. M.

*Preparation of a Substitute for Caoutchouc.* Dingl. Polyt. Journ. p. 255, 215, 1885.

ACCORDING to J. Haug and C. Hoffmann, St. Petersburg, a substitute for caoutchouc is made by washing the skins of hares, rabbits, and other small animals in water, removing the hair in lime-water, and then boiling them, along with 5 per cent. commercial glycerine and a small quantity of water, in a Papin's digester until solution takes place. A thick tough mass results, which can either be dried on wire nets or immediately worked up further. Twelve parts of this mass are melted, along with twelve parts glycerine, in a water bath, and then one part of a concentrated solution of bichromate of potash is added. The liquid mass is poured into moulds, and allowed to harden under pressure. This mass resembles vulcanised rubber, and can better withstand heat. —W. M.

*Recovery of Waste India-Rubber.* A. Gutensohn, London, and A. Cox, Bristol. Eng. Pat. 1994, January 23, 1884.

The seraps, cordings, India-rubber cloth and so on, are first classified into three groups: (a) those containing iron and steel, (b) those in which the adherence of the rubber to the cloth is not great, and (c) those in which the adherence is considerable. Group (a) is put in a solution of copper, such as sulphate or nitrate of variable strength, according to the material to be treated, the iron dissolved and copper is precipitated. The pieces of fabric are then added to (b) or (c) as the case may be. Group (b) is placed in hot water containing a little ammonia. After a short time the rubber can be easily stripped from the cloth. Group (c) is placed in a bath of ammonia diluted with water to a degree variable with the character of the pieces treated. In two or three days, more or less, the rubber can be easily stripped. —J. T.

\* Note by Abstractor.—The author does not state precisely what the term granulose should include, but from the context it would seem to signify the substance of starch granules other than cellulose.

*Improvements in Apparatus for Mixing and Elevating Sugar in Course of Process.* J. H. Johnson. Communicated by "La Compagnie de Fives-Lille," of Paris, France. Eng. Pat. 2344, January 29, 1884.

THE apparatus constituting this invention is principally applicable to the mixing and elevating of sugar in the state of massecuite and other saccharine products, prior to their treatment in the centrifugal machine or turbine, but is applicable for treating other pasty or semi-fluid materials. "The employment of the said mixing and elevating apparatus is attended with considerable advantage in the manufacture of sugar, as the expense of conveying the sugar from the backs to the centrifugal apparatus is entirely obviated, the mixing apparatus being arranged to receive the sugar directly from the backs or other receptacles, and to mix, elevate, and deliver it directly to the centrifugal apparatus. The materials are thus transferred from one apparatus to the other without the intervention of hand labour, and without the waste which ensues during the operation of charging the centrifugal machine by hand. The improved apparatus enables the materials that are to be treated in the centrifugal machines, or turbines, to be mixed and elevated with facility and economy, and may be either permanently fixed in the vicinity of the backs or receptacles containing the said materials, or mounted on wheels so as to enable it to be readily moved from place to place." The apparatus consists essentially of a forcing apparatus, or pump, acting in combination with a mixing cylinder, which stirs and mixes the materials and reduces them to a state fit to enable them to pass readily through the pump. "The apparatus can stand at a very small elevation from the ground, and consequently admits of being fixed and charged with great facility. It occupies but little space, and the cost of its construction is not great." When the apparatus requires to be moved frequently, in order to be brought up close to the backs, or receptacles, containing the massecuite or materials that are to be mixed and elevated or transferred to the centrifugal machines or other apparatus, it is preferably mounted on wheels and actuated by a small independent engine, supplied with steam either by means of a pipe capable of being readily connected and disconnected with or from steam supply pipes of the works, or by a small independent boiler attached to the apparatus.

—H. A. R.

*A New Colour Starch.* Emil Capitaine, London. Communicated by Drumm & Co., Kaiserslautern. Eng. Pat. 5260, March 21, 1884.

THIS invention consists in mixing with starch in the course of its manufacture any suitable brown or yellow colouring matter, so that when an aqueous solution is made of this colour starch, it simultaneously, with the starching operation, communicates a cream colour to goods steeped therein. Any required shades can be readily obtained either by mixing varying quantities of the colouring matter with the starch, or else by making the starch very strongly coloured in the first instance, and then adding the necessary quantity of ordinary white starch.—W. M.

*Improvements in Gloss Starch.* W. H. Carman, of London. Communicated by Wendel Zwick, of Newmühle-Albersweiler, Germany, starch manufacturer. Eng. Pat. 12,326, September 12, 1884.

THE following mixture is claimed as a substitute for borax in giving a gloss to starch or linen. It is stated that the action of borax is very detrimental. The inventor takes from 2 to 5 lb. of white wax, stearine or spermaceti according to the gloss required, and perfumes with about 20 drops of otto of roses, fennel oil or oil of aniseed (or any other suitable essential oil). The melted mixture is then treated with about half-a-pound of caustic soda lye of 10°. After some further boiling, the melted mixture is diluted with about 4 gallons of water. "The above quantities are about sufficient to make 2 cwt. of gloss starch." The fluid is mixed with the starch in a half-dry state, and the water is removed in drying pans. The

wax, stearine or spermaceti, and the volatile oils remain with the starch, which is dried and treated in the usual way. Besides the gloss said to be imparted, the inventor claims a beneficial action of the above mixture on the fabric.—H. A. R.

*Process for Extracting and Saccharifying Ingredients of Amylaceous Substances by Treatment with Malt.* John Inray, Chancery Lane, London. Communicated by Leon Cuisinier, Paris. Eng. Pat. 14,271, October 22, 1884.

THIS specification contains much detail for the treatment of amylaceous materials, by which the starch is converted into dextrin, maltose and soluble substances, for use in the brewery, distillery or syrup factory. The claims bear especially upon a maceration in presence of malt and subsequent heating to a temperature not exceeding 75° C., by a source of heat also not exceeding that temperature, whereby the starch is converted mainly into dextrin. A further addition of malt to the liquor cooled to 50° C. carries the conversion into maltose and readily fermentable sugars.—W. M.

*A New or Improved Manufacture of Filtering, Disinfecting, Deodorising and Decolourising Medium.* G. H. Ellis, Exeter. Eng. Pat. 14,774, November 8, 1884.

LIGNITE or Bovey coal, found in the Bovey basin, near Bovey Tracey and Newton Abbot, in the county of Devon, and containing, when calcined, from forty to eighty per cent. of siliceous matter, with a small quantity of alumina and iron, is subjected to a red heat in retorts and superheated steam introduced, which has the effect of removing the volatile hydrocarbons more readily, and also of extracting portions of the sulphur. The residue is transferred to tanks, and allowed to cool. It is then ground to powder as may be required, or it may be quenched by throwing water over the carbonised material immediately it is withdrawn from the retorts. The material known as "deads," found in association with the lignite beds, and consisting of an admixture of carbonaceous matter and detached particles of lignite, with clay, is treated in a similar manner. This filtering material is said to possess the following advantages:—(1) It is superior to animal charcoal for water filtration, inasmuch as it is free from calcium phosphate. (2) It does not favour the growth of the lower forms of animal life, but is an active agent in their destruction. (3) It is valuable for the filtration of acids. (4) It can be manufactured and supplied at less than half the price of animal charcoal. (5) It is a good deodoriser and decolouriser; and (6) it can be used with economy and advantage for sugar refining, as it causes less waste, in consequence of retaining less of the saccharine matter.—D. B.

## XVL.—BREWING, WINES, SPIRITS, Etc.

*Perret's Wine Fermenting Vat.* Dingl. Polyt. Journ. 254 [12], 486.

MICHEL PERRET recommends a process introduced by him with success twenty years ago, for avoiding the evils attending fermentation in presence of the husks. The

husks tend to rise to the surface of the must, giving rise to acetic fermentation, and a higher temperature in the upper portion of the vat. Perret's vat provides that the

husks are kept in fairly equal distribution throughout the progress of fermentation. To do this, it is fitted with vertical supports, carrying pins inclined downwards, whilst hurdles are laid in horizontally, which rise with the must during the filling, but are kept submerged at

different depths by the rows of pins. The husks are arrested in their ascent by the hurdles. When the wine is run off, the husks and hurdles come down together, the latter falling readily on account of the downward inclination of the pins.—G. H. E.

*On the Amount of Extractive Matter in Wines of the Year 1882.* A. Henneke. *Biedermann's Cent.-Blatt.* 1883, 6, 424.

ACCORDING to the author, the wines of the year 1882 contained exceptionally small proportions of extractive matter, sugar and alcohol, this circumstance being explained by the fact that the vintage was by no means a good one, large quantities of the grapes being more or less unsound.—E. G. C.

*The Preparation of a New and Improved Substance to be used in the Manufacture of Alcohol.* Herbert John Haddan. Communicated by Constant Coster, Brussels. Eng. Pat. 2330, January 29, 1884.

SLICES, pulp, or juice of Jerusalem artichoke, is submitted to the action of acids, sulphuric by preference, or malt! When acid is used a steam pressure of from 1 to 3 atmospheres is employed according to the quantity of acid, but the material is heated under a pressure of 3 atmospheres, then cooled to 50° C. before it is submitted to the action of malt. The syrup obtained is called "glucose of Jerusalem artichoke," and is said to be completely fermentable in 12 hours. The improvement claimed is the saccharification under pressure, and the preparation thereby, of a syrup richer in alcohol-yielding matter, and more rapidly fermentable than is obtained by the process called the "Procédé Champenois."—C. O. S.

*Improvements in the Process of Fermentation and in the Manufacture of Alcohol, Beer, Wine and the like.* Johan Henri Loder. Eng. Pat. 8800, February 4, 1884.

THESE improvements consist in adding various substances such as aniline, orthomononitrophenol, sulphocyanide of potassium, etc., to fermenting liquids.—C. O. S.

*Improvements in the Process of Fermentation in order to Prepare Alcoholic Solutions of Colouring Matters.* Johan Henri Loder. Eng. Pat. 2666, February 4, 1884.

NITRIC acid, trinitroresorcin, orthomononitrophenol, with sulpho-cyanic acid, aniline and sundry such things are added to fermenting liquids, and it is claimed that

alcoholic solutions are thereby obtained which may be employed for the fabrication of wines—red, white or sparkling ones—and by distilling them for the fabrication of an alcohol containing aromatic principles; they may serve to prepare vinegar (*sic.*) or also for dyeing purposes.—C. O. S.

*Improvements in the Treatment of Grain or other Materials for the Production of Alcohol therefrom.* G. Epstein, London. Eng. Pat. 6557, April 19, 1884.

THE patentee aims at conducting the operation of mashing and distilling in a continuous manner. He also states that he has found it more advantageous to work with a strong wort than with a weak one; a density of from 30° to 50° on Sykes's saccharometer gives results. The mashing is conducted in the usual manner, and either acid or diastase may be used. The apparatus specified consists of three parts: (1) the converting vessel provided with a stirrer and steam coil, (2) a straining and cooling vessel, (3) a fermenting vessel. The mode of working is as follows:—After the grain has been mashed it is allowed to descend into the cooling vessel, in the upper part of which is a straining plate; when the temperature has reached the proper point it is run into the fermenting vessel, which is closed to the air, and fermentation commenced; the air requisite to the operation being supplied by a pump. When the attenuation has proceeded far enough, it is forced by the pressure of the carbonic acid gas, given off during fermentation, back into the converting vessel, fresh material is added and another mashing operation started. The alcohol distilled off by the elevation of temperature passes into the rectifier, and the operation first described is repeated. If acid be used for the mashing, the quantity used in the second mash may be smaller than in the first stage. The patentee claims generally the process as described.—C. C. H.

*An Improved Method of and Apparatus for the Preparation of Malt.* Henri Seney. Eng. Pat. 6620, April 21, 1884.

THE grain is steeped in the usual way, and then distributed on rotating endless "aprons" made of wire gauze, placed one above the other in a series of four, and overlapping each other alternately. The thickness of the grain is regulated by adjustable registers, placed above the apron, and at right angles to the direction of its motion. The grain distributed on the top apron is carried forward, and falls on to the next below; this again carries it onward, and allows it to fall on the third apron, and so on until the fourth is reached; from this it is taken up by elevators, and again distributed on the top apron, and the process continued until the germination is considered complete, when it is passed on to an elevator which carries it to the kiln. The apparatus is provided with a "sprinkler," by which the grain in falling from one apron to another receives the necessary amount of water in the form of spray. The claim is for the elevators, endless aprons, sprinkler, etc.—C. O. S.

*Apparatus for Purifying Distilled Spirits.* W. R. Lake, London. Communicated by the Cushing Process Company, Boston, U.S.A. Eng. Pat. 10,740, July 29, 1884.

IN that class of apparatus in which the liquor is purified and matured, by forcing through it air previously purified and heated, much alcohol is frequently carried away from the condenser by the current of air. The present invention comprises a condenser preferably of cylindrical shape, immersed in a cooler charged with cold water by the port. The condenser is connected with a tank, which contains the spirit to be treated. Hot air is passed into the tank. The condensed spirit passes through holes, and returns back into the tank, whilst the air and uncondensable gases pass away by a pipe.—J. T.

## XVII.—FOOD PRESERVING, MEATS, Etc.

*Process for Preserving Meat.* Dingl. Polyt. Journ. 255, 215, 1885.

MIGNON and ROUART cool meat, fish, etc., in a Carré ice machine to 20°, then quickly transfer these articles to tinplate boxes, and solder them up. Each box has a wooden casing, and this again is enclosed in a vessel which is filled with a freezing mixture, and protected outside by a covering of wood and cork shavings. In one experiment 523 lb., out of an original freezing mixture of 1000 lb. were melted after 46 days, and the temperature in the middle of the freezing mixture had risen to 4°. The meat was perfectly good.—W. M.

*Improvements in the Preparation of Salt, Sulphate, Sugar, and other Antiseptic Substances for use in the Preservation of Food.* E. Sonstadt, Cheshunt. Eng. Pat. 6304, April 12, 1884.

THIS invention consists in adding calcium iodate to any food preservative, or to any mixture of preservatives. The proportions may be from one per cent. up to five per cent., and it may be added in either the solid or liquid form. When the solution is used, the solubility may be increased by the addition of neutral sodium or potassium citrate. The claim is made for the application of calcium iodate in the preparation of antiseptic substances used in the preparation of food.—C. C. H.

*Antiseptic Compound.* William Hibbert, Clarence Street, Cheetham, Manchester. Eng. Pat. 13,358, October 9, 1884.

TO one gallon of a solution of magnesium chloride, 50° T., add ½ oz. magnesium bromide, ½ lb. common salt, and ½ lb. potassium sulphate. The same ingredients may be used in other proportions. The mixture is available for the preservation of meat, and other animal and vegetable substances.—J. M. H. M.

*Improvements in or Relating to the Preparation of Beverages or Foods.* W. H. Thew, Liverpool. Eng. Pat. 14,965, November 13, 1884.

THE object of this invention is to manufacture a preparation of condensed peptonised milk and cocoa, in which the flavour of peptonised milk is disguised, and the constituents of milk are enriched by the addition of the nutritious and stimulant principles of cocoa, in an easily digestible form, also a preparation of coffee and peptonised milk. The milk to be peptonised is heated to about 60° C., then a decoction of cocoa is added and bicarbonate of soda (½ oz. per gallon), or phosphate of soda (½ to 2 oz. per gallon). An extract of pancreas is next added, the mixture kept at about 60° C. for 1-2 hours. By the action of the pancreatic ferment, the insoluble constituents of the cocoa are rendered almost completely soluble. When the peptonising is finished, sugar is added and the liquid is boiled for a few minutes, to kill the ferment, and then concentrated in a vacuum pan, until it contains about 20 per cent. of water. In preparing condensed peptonised milk and coffee, an extract of coffee is added to the peptonised and sweetened milk, preferably during the later stages of condensation.—W. M.

## XVIII.—SANITARY CHEMISTRY, DISINFECTANTS.

*Spread of Cholera through the Medium of Water.* Dingl. Polyt. Journ. 254, 444.

MAREY (*Compt. Rend.* 99, 667) shows from the cholera reports of the year 1832, 1849, 1850, 1854-55, that the spread of the epidemic in the various districts of France where the disease raged, is distinctly traceable to contamination of water supplies. This confirms the statements of Koch (*Dingl. Polyt. Journ.* 252, 261).—C. F. C.

*Communication of Cholera by Drinking Water.* The Medical Chronicle [6], 518-522. Abstracts from various Reports, etc., by Prof. J. Dreschfeld.

Koch's results have been already briefly given (see this Journal, iv. [1], 59). The investigations of the English Commission, as reported by Klein, have led them to the following conclusion, among others. There is direct evidence to show that water contaminated with chloroæria evacuations, and containing, of course, the comma bacilli, when used for domestic purposes, including drinking, by a large number of persons, did not, in the case of the tanks near the Sahel Bagan, produce cholera. Dreschfeld remarks with regard to this evidence: "Against this negative evidence Koch would cite his positive evidence, as seen from his report." Pettenkofer speaks chiefly against the contagious nature of cholera, especially against its propagation by drinking water. His statement about the disappearance of the cholera from Fort William, with the improved drainage of the Fort, is contradicted by De Renzy, who clearly showed that the cholera disappeared with the improved supply of drinking water. Klebs, in his second paper, gives an interesting instance of the propagation of the cholera by contaminated drinking water. Genoa is supplied with water by the Acqua Nicolay, Acqua Galliera and the Civico Acquedotto. Of 270 cases of cholera, where the water supply could be determined with precision, 256 received their drinking water from the Acqua Nicolay—i.e., 92 per cent. The workhouse, with 1200 inmates, is supplied from the Acqua Nicolay, but the supply was cut off immediately after the cholera broke out, and though the cholera raged in this district, by no means a very salubrious one, no case of cholera occurred in the workhouse. As to the source of the contamination, it was found that cholera cases occurred nine to ten days previous to the outbreak in Genoa in the small village of Busalla, situated near the mountain river Scrivia, whence the Acqua Nicolay draws its water supply; the bed of the river is very stony and the water very shallow, and it is well known that the inhabitants of Busalla dried their clothes on the stones standing out from this brook.—W. S.

*Improvements in the Preparation of Agents to be used in the Treatment of Sewage and other Similar Putrescible Matters.* W. C. Sillar and J. W. Slater, Kent and Middlesex. Amended specification. Eng. Pat. 1144, September 3, 1883.

THE inventors prepare crude chloride of aluminium or chlorides of aluminium and iron, for use in the purification of sewage, etc., in the following manner. An aqueous solution of sulphate of alumina (obtained, for example, by lixiviating with water any shales or other minerals containing sulphate of alumina either alone or together with sulphate of iron) is mixed with solution of calcium chloride, in equivalent proportions, the deposit of sulphate of lime then formed is used for manurial or other purposes, and the liquid—which consists, according to circumstances, of a solution of aluminium chloride or of the chlorides of aluminium and iron—is employed for the purification by precipitation of sewage, etc.—E. G. C.

*A New Disinfectant.* Alfred J. Shilton, Birmingham. Eng. Pat. 852, January 7, 1884.

THIS preparation consists of a solution in water of potassium iodide, iodine and chloride of ammonium, the proportions being 2oz. of potassium iodide, 1oz. of iodine, and 16oz. of ammonium chloride, to each gallon of water. The disinfectant may be diluted for use with 15 or 20 times its bulk of water, and either exposed to the air in shallow vessels or diffused by means of a spray producer.—E. G. C.

*An Improved Compound for the Elimination of Dissolved Matter from Water.* P. A. Maiguen, London. Eng. Pat. 3038, February 9, 1884.

THE improved compound is the mixture, in a powdered form, of substances "of a differential order of action" to precipitate the salts in a water. The patentee states

that the consequence of the addition of such a mixture is the successive precipitation of the various inorganic bodies present, the reactions occurring seriatim, with a "slight overlap." The materials composing the mixture may be lime, alum or sulphate of alumina, etc., "calcined or ground soda or soda-ash"; but the proportions and the materials themselves may undergo variation "so long as they constitute a compound in a powdered state of chemical equivalents with constituents of differential order of action." The claims are: (1) The compound composed of the re-agents specified above with the alternative addition of permanganate of potash; (2) an alternative compound composed of "chemical equivalent in a powdered state acting upon the water in the same differential order as hereinbefore described."—C. C. H.

*Improvements in and Relating to the Filtration and Purification of Water and means Employed Therefor.* W. R. Lake, London. Communicated by J. W. Hyatt, Newark, New Jersey, U.S.A. Eng. Pat. 3593, February 19, 1884.

THIS specification describes a method and apparatus for the continuous purification of water. The process consists of injecting into the water, whilst on its way to the filtering bed, any substance, such as iron or salts of iron, which will coagulate the impurities succeeded by a re-agent—e.g., lime or the alkaline earths which combines with the first re-agent and precipitates the excess of the iron. The water is then passed on to a bed of filtering material preferably composed of sand and comminuted iron; the precipitated matters are retained on the filter and the water issues from the apparatus bright and clear. The apparatus consists of a water meter, also actuating an automatic injector adjusted for forcing the proper amount of re-agents into the water and a vessel holding the filtering bed. The whole invention is covered by six claims.—C. C. H.

*Improvements in Disinfecting Litter Powder or Composts.* J. Brown, Dewsbury. Eng. Pat. 5175, March 20, 1884.

IN order to prevent the spread of infectious diseases, such as "foot and mouth disease," among cattle the patentee manufactures a disinfectant litter by saturating sawdust, peat or other fibrous or absorbent vegetable matter with carbolic acid and creosote: fifty per cent. of the acid and five per cent. of creosote giving good results. The claims are: (1) The manufacture of a disinfectant litter from vegetable matter or porous earth by the addition of carbolic acid and creosote; (2) the use of the litter for the purpose set forth.—C. C. H.

*Improvements in the Manufacture of Carbolate of Lime for Disinfecting and Deodorising Purposes.* J. B. Austin, Bristol. Eng. Pat. 5447, March 25, 1884.

TO produce a cheap disinfectant the spent lime from gas works is heated to drive off the sulphur, carbonic acid and other volatile products, which have combined with it in the purification of the gas. It is then combined with 25 per cent. or more of carbolic acid, producing a carbolate or sulpho-carbolate of lime. To produce a mixture of uniform composition it is passed through a disintegrator or other apparatus. The claim is the manufacture of a carbolic powder from the refuse lime of gas works treated as described.—C. C. H.

*Improvements in Apparatus and Arrangement of Apparatus for Filtering Water and other Fluids.* G. Weddell, Newcastle-on-Tyne. Eng. Pat. 6208, April 10, 1884.

THE filtering apparatus is constructed in two parts, the upper part receiving the unfiltered water and the lower part the filtered water. Between the two there is placed the filtering chamber; this consists of a cylindrical vessel packed with animal charcoal and covered at each end with paper, cotton, or asbestos cloth, the whole filtering medium being retained in place by perforated diaphragms of porcelain, glass, or other suitable material. The patentee claims as novel the filtering chamber, as described and arranged.—C. C. H.

*Improvements in Disinfecting Powders.* C. Lowe, Reddish. Eng. Pat. 6401, April 16, 1884.

A MIXTURE of refined carbolic acid, cresylic acid, or other coal-tar acids, in a concentrated state, is mixed with infusorial earth or "Kieselguhr;" such earths are capable of absorbing an equal weight of the acids named. The proportions usually employed are 40 to 75 parts of the concentrated acids to from 60 to 25 parts of the infusorial earth. This powder is specially suitable when heated in vessels for disinfection by the vapours of the acids. The patentee claims the manufacture of the powder as described.—C. C. H.

*An Improved Method of Purifying Water Contaminated by Dissolved Vegetable Matter.* A. Irving, Wokingham. Eng. Pat. 8056, May 22, 1884.

THE patentee states that the vegetable matter contained in a water is held in solution by means of certain organic acids. The removal of these may be effected by bringing the water in contact with metallic iron when the soluble salts of that metal are formed; exposure to oxygen at once causes the precipitation of the iron as the peroxide, the acids being resolved into carbonic acid and water to carry this into effect for small quantities of water such as used for domestic purposes. The specification shows a filtering apparatus consisting of a reservoir for holding the iron deep enough to contain sufficient water to keep it covered, a filtering bed of sand and gravel, an air chamber through which the water falls and becomes aerated, a conical piece covered with cloth to separate the oxide of iron precipitated by oxidation, and a receiver for the purified water. In operating upon large bodies of water the iron is brought in contact with it in shallow ponds or lakes, the required amount of oxygen furnished by causing the stream of water to fall over a succession of cascades, and the precipitation oxide of iron removed by filtration through beds of sand. The claims are (1) the process as described, (2) the small domestic filter, (3) the process for purifying large quantities of water as specified.—C. C. H.

*Improved Process for the Manufacture of a Mineralised Carbon for Filtering, Disinfecting, and other Purposes.* J. W. Gatehouse, Bath. Eng. Pat. 9102, June 17, 1884.

THE inventor intimately blends with lignite (preferably dried and granulated) mineral matter containing large amounts of silica, either free or combined, such as felspar, diatomaceous earths, grit stones, sandstones, volcanic tufa, greenstone, siliceous clays, etc., in such proportions that the product obtained by distilling the mixture in suitable retorts shall contain from 20-60 per cent. of mineral matter, and from 80-40 per cent. of carbon, according to the purpose for which it is required.—E. G. C.

*Improvements in the Collection, Treatment and Disposal of Sewage, etc.* Donald Nicoll, Westminster. Eng. Pat. 10,275, July 17, 1884.

THE inventor calls his method the "Cloacina" system, and he collects the excrementitious refuse from dwellings in metal tanks of suitable sizes and shapes, each possessing a removable air-tight cover and containing two framed metal strainers (also removable) so arranged as to divide the tank into two compartments; one of the latter contains sand, grit, gravel or other similar material, and the other is filled with animal or vegetable charcoal. Each tank has an opening in the lower part of one of its sides, masked by galvanised iron-wire network, and serving for the escape of the effluent, which is "perfectly innocuous, and can be discharged with safety to the public health down any open ditch, sewer, river or watercourse." These tanks are to be placed, with their lids off, in subways faced with non-absorbent bricks and constructed in the footpaths or as near as possible to the dwellings, the sewage from which is to be received. Over each tank is a manhole of framed ironwork, coated outside with the usual paving of stone, metal, or asphalt, as the case may be. From time to time the manholes are opened and, by means of a funnel, dry earth, crushed

burnt clay, street mud, lime, salts of alumina, sifted dry ashes, or soot, as may be preferred, can be shot down upon the matter in the tanks beneath. When sufficiently charged these are to be removed in wagons provided with cranes and hand-winchies for the purpose of hauling the filled tanks out of the subway and replacing them by empty ones. During the removal of the charged tanks their air-tight covers are screwed on, and the lateral outlets before referred to are also closed by screwed lids. The wagons are furnished with flanged wheels, gauged for the nearest tram or railway, and with removable broad wooden tyres so that the operations of moving the tanks, depositing street mud, etc., can be carried on at night with as little noise as possible. A further part of this invention relates to the treatment and disposal of the sewage matter collected in the tanks, and consists in the construction of fireclay kilns, with double roofs, so arranged that offensive vapours pass through perforations in the inner roof and are conveyed back to the fire by a return or connecting pipe. The charged tanks are placed in these kilns for the purpose of drying, not charring, the contained sewage matter, which is thus solidified and rendered suitable for pulverisation and sale in the form of a powder, similar to that known on the Continent as "poudrette." In rural or thinly-populated districts pits are to be substituted for the above-mentioned subways, for the reception of the tanks.—E. G. C.

*Hygienic Candles.* A. Wright, London. Eng. Pat. 11,963, September 3, 1884.

TALLOW, stearine or other material used for making candles is mixed with 5-10 per cent. of oil of eucalyptus or caperput oil, or a mixture of these. In some cases a small proportion of carbolic acid may be added.—J. T.

## XIX.—PAPER, PASTEBOARD, Etc.

*Manufacture of Paper capable of Resisting Fire and Damp.* Dingl. Polyt. Journ. 1884, 254, 315. Ger. Pat. 28,139, December 21, 1883.

W. HERRE proposes to add to the pulp during the process of grinding in the rag-engine solutions of certain salts which, by mutual decomposition, form insoluble compounds. The solution which is added first contains zinc sulphate, or chloride, or calcium chloride, or acetate, whereupon tallow, soap, glue, and alum are added. After having been thoroughly mixed the mass is formed into paper, which, however, before being dried is once more passed through a bath of the same, or similar, composition to the solution used for mixing with the pulp in the rag-engine, and ultimately impregnated with a solution of catechu.—F. M.

*Preparation of Cellulose for Paper-making.* Dingl. Polyt. Journ. 255 [3], 111.

A. BEHRN COETHEN has patented the following process (Ger. Pat. 28,219, September 29, 1883) for preparing cellulose and glucose from wood: After being carefully barked and cleaned, the wood is reduced to shavings or sections in A (Fig. 1). The sections pass through a trap *a* on the drying loft *b*, and are there subjected to preliminary desiccation, after which the wood passes through *c* on to the drying loft proper, B. The base of the same consists of perforated iron-plates. Canals *e* introduce fresh air under the base, which is heated by a system *f* of tubes fed with condensed water. Hot-air passes into B, and B, then through the loose wood drying the same, and finally escapes by the canals *g* to the flue. If the wood is subsequently to be treated with alcohols, it is necessary to remove turpentine from coniferous woods by a distillation at 160° C. By means of the hopper *h*, and the manhole *i*, the wood is passed into the iron cylinder C, which is furnished with an agitator.

The cylinder is jacketed in its lower half; and the jacket fed with steam of six atmospheres. The sub-

sequent drying of the wood takes place by means of the water which has been used for cooling the worms, etc. Water or steam is introduced by the cock *l*, and passes out by *m*. After closing the manholes and the cocks *n*, the cocks *o* are opened, until enough steam has passed in through *p*, which follows the side of the cylinder. The turpentine (*b. pt.* = 157° C.), mixed with aqueous vapour, passes through *q*, *r*, and *s*, to the cooler *t*, where the gases are liquefied, and flow into S. After all turpentine has passed over, steam and cock *o* are shut off, and *n* and *v* opened. The agitator brings the wood into contact with fresh air coming in through *n* and *p*, and escaping through *v* and *w*, into the flue. After being dried the wood is conveyed by means of D to the first floor, and thence into the boiler E, where it is to be freed from resin. When filled, two-thirds with wood, oil of turpentine, or fusel oil, is introduced from G by means of *u* and F, so as just to cover the wood.

By means of *h*, the temperature is brought somewhat over that of the liquid contents, and an excess of pressure in the cylinder avoided by the cooler *c*. When all resin is dissolved the pulpy mass is conveyed into the extractor H, through *f*, and *g*. A false bottom *h*, allows of the removal of the resin solution by means of steam. In the receiver J, separation takes place, the resin solution forming the upper layer on the water containing extractive matter. The former is distilled in K, and the latter conveyed to the receivers R and M, over the glucose boiler. The pulp remaining in the cylinder, on the false bottom *h*, contains usually certain carbohydrates and salts insoluble in water; and in the case of coniferous woods the salts of iron present much impede subsequent bleaching. This pulp is conveyed into the glucose boiler O, and there treated with the required quantity of very dilute sulphuric acid. After boiling, the pulp is washed till free from acid. The waste liquor from this operation contains notable quantities of glucose; and is, therefore, also conveyed to the cisterns P. The pulp is then ready for bleaching, or else is pressed and dried.

W. FLOLQUIST'S process (Figs. 2, 3, and 4), according to *Papier Zeitung*, 1884, p. 1436, differs from other sulphate processes, mainly in the fact that the SO<sub>2</sub> passes over moist bones, which have been freed from fat, and so produces a solution containing bisulphite and phosphate of lime. The SO<sub>2</sub> passes through *g*, and with the trap *w* placed as in Figs. 2 and 4, follows the arrow-head through *a*, *i* and *k*, into the first absorption chamber L. Of 10 chambers two are supplied with bones, and eight with limestone. The action is continued until the solution in D has the required density of 5° B. for wood, which is reduced to 2.5° B. for straw. For particulars respecting the management of the apparatus, and the preparation of glue, etc., the original should be consulted, as these are incapable of useful abstraction.

The arrangement for preparing paper-pulp consists mainly, as shown in Fig. 5, of a spherical revolver, fed direct, at high pressure, and hence provided with a safety valve *l*. The boiler is made of steel plates lined with lead, which is alloyed by means of screws provided with large lead-covered heads.

When pulping sawdust, the same is filled into about half the boiler, covered with the above solution, and then boiled for eight or nine hours, with a final pressure of about 70 lb., and with four revolutions per hour. The boiled mass is then reduced as required. Wood is boiled similarly to sawdust. For straw, after chopping, comes a six hours' boil with the lye at 2.5° B.—H. A. II.

*Improvements in the Manufacture of Paper.* John Henry Johnson. Communication from Jules Andre, Meyrueis. Eng. Pat. 151, January 1, 1884.

THIS process, which does not appear to contain any novelty, consists in causing two webs of paper of different quality, while still wet, to combine together by pressure. Thus united, the duplex paper is dried and finished in the ordinary way. The specification is accompanied by drawings, showing how the method can be worked either with two cylinder machines or with a combination of a cylinder and an ordinary Fourdrinier machine.—E. J. B.

*Improvements in the Manufacture of Paper, Paper Pulp, Pasteboard, Millboard and Papier Maché, and such substances applicable for Cabinet and all kinds of Structural Purposes.* Eng. Pat. 2316, January 29, 1884.

This remarkable process consists in boiling peat, moss or wood fibre, in a liquid composed of potash, chloride of lime, quicklime, sulphuric acid and acetic acid. Pulp so prepared is bleached by a solution containing the above reagents, together with sulphur.—E. J. B.

*Improvements in Uninflammable Pulp for Paper.* Baron Louis Moser Dulfus, London. A Communication from Julien Ponty, of Brussels. Eng. Pat. 3780, February 22, 1884.

The object of this invention is to produce a material in itself uninflammable and incombustible, which, when applied to the manufacture of paper, etc., will render the same capable of resisting a fierce fire. This material is also to have the important property of constituting an insulating material for electrical conductors of all kinds, and to be not attacked by acids or corrosives. The principal constituents of this uninflammable powder are: (1), asbestos fibre, which is reduced and bleached in any convenient way; (2), fossil powder, which is a substance containing about 80% silica, 10% fossil wood, 5% lime and 5% iron, and which is bleached by chlorine or otherwise. This material, when crushed, is mixed with an equal quantity of "neutral" silicate of soda at 40° Bc. Besides its uninflammability, this light material has the property of rendering the paper soft to the touch, and of affording a good hold for the size, "as each particle is hollow." In some cases this material may be replaced by sulphate of alumina, or any other uninflammable material; (3), a pulp obtained from animal fibre—e.g., waste silk, silk rep, or other materials having similar qualities as regards cohesion and felting properties combined with fineness of fibre, which will thus not flare up when ignited. A pulp from Baobab bark, which has these properties, may be substituted for the silk or other pulp. The proportions will vary according to the nature, etc., of the paper to be produced. For fine writings the following proportions are recommended:—

Asbestos .....	80-90%
Fossil powder .....	5-10
"Neutral" silicate at 10 Bc .....	5-10
Animal (silk) pulp .....	1-5

If the sizing to take place in the engine, 1% of the following "size" must be added:—

Water .....	130 parts.
China clay .....	100 "
"Neutral" silicate at 30° Bc .....	9 "

When the paper is to be tub-sized, the water and China clay will be 65 and 47 parts respectively, and 12 parts of resinous soap are added. For moulding ornaments direct from the pulp, or for coating electrical conductors, the proportions are somewhat altered, and a small quantity of ceresine added. The following proportions are recommended for such a case:—

Asbestos .....	70-80%
Fossil powder .....	10-15
Silicate at 35° Bc .....	5-10
Silk pulp .....	1-3
Ceresine .....	1-5

In applying this pulp for insulating wires, the coating varies from 1.5mm., and if the wires are submarine, some suitable non-putrescible material is added.—H. A. R.

*Improvements in Means for Rendering Objects Uninflammable.* Baron Moser Dulfus, London. A communication from Julien Ponty, of Brussels. Eng. Pat. 3786, February 22, 1884.

INFLAMMABLE objects, such as theatre decorations, are to be rendered uninflammable as follows:—The object to be rendered incombustible is covered with paper made according to specification No. 3780 of even date. This paper is affixed by means of a special uninflammable adhesive mixture, which is composed of 80-85 per cent. of sodium silicate of 40° Bc. mixed with from 10-15 per cent. of fossil powder ground fine. After two or three days the mixture is to be decanted and used.—H. A. R.

*Improvements in the Method or Process of, and Apparatus for, Draining, Concentrating, Clarifying, and Consolidating or Solidifying Substances and Liquids, especially applicable for Filtering Paper Mill Sludge, and Consolidating the Substances contained therein.* J. Foulis, Musselburgh, N.B. Eng. Pat. 4202, March 1, 1884.

THE object the patentee has in view is the separation of the solid from the liquid matter contained in a material such as the refuse waters from a paper mill. The material is first settled in tanks in order to eliminate as much of the water as possible. The residue is then submitted to pressure in a suitable apparatus, of which two kinds are described. The first kind of apparatus shown is similar to a paper-making machine; the sludge is fed on to an endless band and carried between rollers, the upper one bare, the lower covered with felt. The pressure eliminates a further quantity of water, which is absorbed by the felted roller, the solid matter adhering to the bare roller, and being scraped therefrom by a blade, is carried on to the next pair of rollers, where it is similarly treated. The second form of apparatus shown resembles a filter press with a single cell. A cylinder is fitted with a cover, the face is grooved and covered with felt, a piston fits the interior of the cylinder, the face of which is similar to the cover, and it can be drawn back or forced forward by a hydraulic ram; the material is admitted to the interior of the cylinder by a valve which does not permit egress of the liquid when pressure is applied. The cylinder being charged with the sludge by drawing back the piston, the pressure is applied and the water expressed out; on drawing back the piston, a second charge is admitted, and the operation repeated until a solid cake of the matter recovered is left in the machine. In some cases the liquid is heated before being subjected in order to coagulate the albuminous matters.—C. C. H.

*Improvements in Apparatus for making Wood-Pulp.* W. R. Lake. Communicated by C. Storey, of Providence, Rhode Island, and George E. Marshall, of Turner's Falls, Mass., both in U.S.A. Eng. Pat. 12,346, September 12, 1884.

THIS invention relates to the apparatus used in making wood-pulp, and comprises the following objects: Reduction in the cost of production, firstly by facilitating the operation, and secondly by reclaiming to a large extent the chemicals employed. Also the simplification of the process by rendering it more automatic than has hitherto been the case. Further to simplify the process of constructing the digester used in the operation, and finally to provide the same with an improved lining which shall meet the requirements of the operation. In the present process for disintegrating woody fibre, by boiling under pressure. Sulphurous acid is used to dissolve the resinous and other cementations mantle enclosing the said fibres. The liquid in which the fibre is boiled is water, containing from one to four per cent. of sulphurous acid in combination with lime or magnesia in varying proportions. This liquid covering the fibres is heated in a jacketed boiler of a non-corrosive metal. A steam space is left in the upper part of the boiler. Whilst the boiling is proceeding large amounts of gases are produced, and which take up oxygen from the water, fibre and chemicals forming sulphuric acid which may injure the fibre by too violent action. Hence occasional blowing off is required, and this entails considerable time, attention and care, besides the gases being totally lost. Another difficulty lies in the sudden expansion of the gases by which the top-pressure in the digester is increased, and the free circulation in the interior is interfered with. To avoid these difficulties and to prevent the loss of chemicals, the steam space of the digester is connected with a condenser surrounded with cold water, and regulated by some form of a steam-trap or valve by which any liquid having condensed is automatically removed without any reduction in the steam pressure of the digester. When blowing off the chemicals are reclaimed by a separate condenser connected with a tank fitted with stirrers by means of which the acid can

be again combined with any desired base, or be otherwise utilised. By this improved apparatus the pressure is gradually raised, but accumulation of gas and consequently of pressure avoided, the circulation made rapid, and hence all parts of the charge are brought under the action of heat and of the liquid. The burning or blackening of the fibre from the formation of sulphuric acid is also prevented. The chemicals not taken up by the cementitious matter are regained, the attention and labour required are reduced, and a superior and more uniform product than hitherto is obtained.—H. A. R.

*Improvements in and Relating to Boilers for use in Treating Wood, etc., with Acids.* H. H. Lake, London. Communicated by C. W. Flogdyst, Gothenberg. Eng. Pat. 15,188, November 18, 1884.

THE object of the improvements is the prevention of the fracture of the lead lining of vessels used for this purpose, and which is due to the buckling produced by the unequal expansion between the lining and shell of the vessel consequent upon heating. Instead of making the lining, and the shell also, in one continuous piece as heretofore, in which case the difference of expansion reaches a maximum, the vessel is made up of a number of flanged pieces, made from steel, cast or wrought iron, each piece being covered with lead also beaten out over the flanges, the whole being firmly held together by bolts; thus forming one vessel with a continuous lining. The complete vessel is provided with lead lined covers fitted with manholes, and in some cases may be suspended on trunnions at right angles to its longer axis, gearing being provided for its revolution when necessary; one trunnion serving for the introduction of steam and the other for its exit. The claims are: (1) a boiler composed of a number of rings bolted together as described; (2) lining the rings with lead flanged over the joints so as to form a packing between the joints of the cylindrical rings.—C. C. H.

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES.

*Santonine Manufacture at Orenburg, Russia.* Dingl. Polyt. Journ. 1884, vol. 254, p. 316.

THE proprietors of the Santonine Works at Orenburg, H. Maier & Co., contradict the statement made by C. O. Cech, of Moscow (Dingl. Journ. 1884, vol. 253, 475), that the said works, after three years' existence with a very modest production, had now entirely discontinued the manufacture of santonine, saying that they had been in full work ever since they have been established. The factory is fitted up in the best possible manner (the boilers being fired with the seed refuse), due regard being taken for enlargements, whereby the future production may be easily raised to three times that of the present (900kilos. per month), in case the demand for santonine should continue to increase.—F. M.

*A Fourth Alkaloid in the Box-tree.* G. A. Barbaglia. Berichte, 17, 2655.

A QUANTITY of alkaloid substances may be extracted from the leaves and branches of the box-tree by the usual method, and these are then treated in the manner given for the separation of the three colouring matters: buxverdin, buxorubin, and buxoxanthin. These substances are dissolved in alcohol, and the liquid neutralised exactly, with an alcoholic solution of oxalic acid. The white precipitate formed is separated, boiled repeatedly with distilled water, dissolved in dilute aqueous oxalic acid, and finally shaken with ether after making alkaline with sodium carbonate. The ethereal solution, after filtering from buxinidin, is concentrated, and on cooling, a new alkaloid, to which the author has given the name of "parabuxinidine," crystallises out. This alkaloid forms thin transparent prisms, insoluble in water, soluble in alcohol. The author intends to complete his investigations on this body.—J. B. C.

*Improvements in the Process of Manufacturing Iodoform, Bromoform, and Chloroform.* Theodor Kempf. Eng. Pat. 8148, May 23, 1884.

THIS invention relates to the manufacture of the above substances by electrolysis from suitable halogen compounds of the alkalis and alkaline earths—in the presence of alcohol, aldehyde, acetone, and of heat. The solutions are electrolysed in an atmosphere of carbonic acid and with constant heating. To obtain iodoform in large crystals, iodide of potassium is dissolved in alcohol of 20% and electrolysed as stated. To obtain bromoform or chloroform, the electrolysis is similarly conducted, but without carbonic acid.—T.

## XXI.—EXPLOSIVES, MATCHES, Etc.

*Process for the Recovery of the Waste Acids from the Manufacture of Nitro-Glycerine.* Dingl. Polyt. Journ. 255, 216, 1885.

ACCORDING to W. Poltsch (Ger. Pat. 29,661, October 31, 1883), when these waste acids, consisting of sulphuric acid, nitric acid, and unknown organic nitro bodies, are heated to 103°, the nitro compounds are decomposed and oxidised, at the expense of the nitric acid, to carbonic acid. So much heat is evolved in this reaction that the still undecomposed nitric acid, along with the lower oxides of nitrogen, is driven off, and pure sulphuric is left. He employs a closed stone or lead vessel, three to four metres high by forty centimetres wide, provided with a false bottom. The upper space is filled with flints. A pipe opening just above the false bottom introduces hot air, whereby the flints become warm. The waste acids are allowed to enter the vessel at the top through a funnel, in thin streams, and passing over the heated flints are decomposed. The oxides of nitrogen, along with the introduced air, pass away by a tube through cooling pipes into a Woulff's bottle, where more air is added, whereby nitric acid is produced. The denitrated sulphuric acid flows through the false bottom, and is led away from the lower space by a leaden pipe.—W. M.

*Improvements in the Preparation of Blasting-powder from Nitrated Cellulose.* W. Gedge. A Communication from W. F. Wolff and Max von Foerster. Eng. Pat. 13,522, October 13, 1884.

THIS plates of nitro-cellulose, prepared either by compressing the finely divided wet substance into sheets or by slicing blocks of the compressed material, are sawn into strips, the strips into grains; or the strips and grains may be stamped out of the plates. The grains may be "coated" by immersing them in a solvent of the nitro-cellulose, or in liquid paraffin with the object of rendering them less liable to crumble. It is stated that by so proceeding, a dense powder is obtained having an effect similar to that of compressed gun-cotton in large pieces.—W. D. B.

*Experiments with Dynamite Cannon.* Dingl. Polyt. 254 [6], 248, 1884.

RECENT experiments conducted at Fort Lafayette with the dynamite cannon briefly described in Journ. Soc. Chem. Ind. 1884, p. 532, have given favourable results. With a projectile weighing 19kilos., and not charged with dynamite, the deviation from the line of sight was 0.61m. (2 range). When the projectile was loaded with charges of ordinary dynamite weighing from 6.8kilos. to 7.6kilos., the deviation in all cases was less than 0.914m. The explosion of the charges formed large craters, from which earth and stones were projected 30m. into the air. Pointing seaward, at an angle of 22°, and with an air pressure of 36 atmospheres, the range of a projectile weighing 10kilos. was 2000m. F. H. Snyder (Scientific American, 1884, 50, 295) adopts the arrangement here figured for projecting from an ordinary 12-pounder Rodmann gun with the usual charge of powder, a shell of dynamite in place of a ball. The premature explosion of the dynamite by the powder used for its propulsion is

sought to be prevented by means of buffers. B is the shell attached to the wooden rod A. In the foremost part of the shell the dynamite is placed, and between the rod and the explosive, the buffer D, consisting of a caoutchouc cylinder with numerous air spaces. E, closed with the tightly-fitting cap K, is provided. When the weapon is employed for naval purposes the wooden rod is of considerable length, and is shaped as shown at C, but when used on shore the rod is quite short and plain. Between the end of the rod and the charge of powder, the buffer arrangement T, S, W, X, L, F,

To avoid these difficulties, the author proposes to use hydrogen peroxide, which is added to an acetic acid solution. Under these circumstances, the whole of the iodine is separated from the iodide, while bromides and chlorides are unaffected.

Details of the methods of employing the test for qualitative and quantitative purposes are given; in the latter case, the iodine is extracted by means of chloroform, the solution is washed with a little water to remove hydrogen peroxide, and the titration of the iodine then effected in the usual manner.

Mr. C. E. Groves and Dr. Stevenson both testify to the value of the nitrous acid method for determining small quantities of iodine in presence of much chlorine.

—W. S.

*A Quick Method for the Estimation of Phosphoric Acid in Fertilisers.* J. S. Wells, Columbia College. *Proc. Chem. Soc.* [3], 20.

FINDING the ammonium molybdate method too long and tedious when many analyses of fertilisers had to be done, the author has adapted Joule's citric acid method as a gravimetric process. He employs two solutions: A, consisting of citric acid 900gm., ammonia solution (rel. den. 0.92) 1400cc., water 500cc.; and B, a strong solution of magnesium citrate. 1gm. of the fertiliser is fused with sodium carbonate and nitrate, dissolved in nitric acid, and the silica filtered off. To the filtrate some of solution A is added, and the whole allowed to stand for half an hour; enough of solution B is then added to precipitate the phosphoric acid. For the author's experiments, a test solution was made up of sodium phosphate, calcium chloride and ammonia-iron alum, so as to contain  $P_2O_5$ , 19.83 per cent.,  $CaO$ , 25 per cent.,  $Fe_2O_3$ , 3 per cent.; equal portions were taken for analysis, the comparison of his results with theory being given in a table. He compares his own method with the ammonium molybdate method on several fertilisers, with the following results:

	Ammonium citrate method.	Ammonium molybdate method.
1. ....	1.23 per cent.	1.23 per cent.
2. ....	18.36	18.15
3. ....	3.42	3.64
4. ....	14.01	13.92

Mr. F. J. Lloyd believes the accuracy of the results as above obtained would depend on, and vary with, the kind of material tested.—W. S.

*The Estimation of Chromium.* H. Peterson. *Dingl. Polyt. Journ.* 234 [6], 271, 1884.

ACCORDING to the author, the methods devised by Blair and Schöell are not to be recommended. The following is considered better: The metal is finely pulverised and 0.5gm. is warmed with 35cc. of dilute sulphuric acid. The solution is treated with a slight excess of concentrated potassium permanganate solution to destroy any soluble hydrocarbons, the ferric sulphate is reduced with zinc,—and, if care be taken to leave a trace of ferric salt, there is no fear of the chromiumsulphate being reduced,—

## XXII.—GENERAL ANALYTICAL CHEMISTRY.

*On Toughened Filter-Paper.* E. E. H. Francis. *Proc. Chem. Soc.* [3], 19.

FILTER-PAPER which has been immersed in nitric acid (sp. gr. 1.42) and washed with water is remarkably toughened, the product being pervious to liquids, and quite different from parchment-paper made with sulphuric acid. Such paper can be washed and rubbed without damage, like a piece of linen. The paper contracts in size under the treatment, and the ash is diminished; it undergoes a slight decrease in weight, and contains no nitrogen. Whereas a loop formed from a strip 25mm. wide of ordinary Swedish paper gave way when weighted with 100-150gm., a similar loop of toughened paper bore a weight of about 1.5kilo. The toughened paper can be used with the vacuum pump in ordinary funnels without extra support, and fits sufficiently closely to prevent undue access of air, which is not the case with parchment-paper. An admirable way of preparing filters for the pump is to dip only the apex of the folded paper into nitric acid and then wash with water; the weak part is thus effectually toughened.

—W. S.

*The Detection and Estimation of Iodine.* Ernest H. Cook, B.Sc. (Lond.). *Proc. Chem. Soc.* [3], 19, 20.

THE usual tests for iodine when existing as an iodide are rendered somewhat difficult by the circumstances that nitrous acid liberates bromine as well as iodine, while, if an excess of chlorine be employed, colourless chlorides of bromine and iodine are formed. These difficulties become of importance when it is desired to detect small quantities of iodides in the presence of comparatively large quantities of bromides, or when a quantitative estimation is to be made of the iodine:

the solution diluted with water to one litre and the iron titrated with standard permanganate. After titration the solution containing much sulphuric acid is heated to boiling, and permanganate solution, of which 1cc. corresponds to 0.01grm. of iron, run in slowly till much peroxide of manganese has separated; or, with greater safety, potassium permanganate is added till the permanent red colour of the solution proves it to be present in excess. The excess is reduced with manganous sulphate, and the solution which now contains the chromium in the form of chromic acid is filtered through a large filter, the residue being washed with hot water. The filtrate when quite cold is treated with a known excess of iron-ammonium sulphate, of which the amount remaining unoxidised by the chromic acid is determined by titration with standard permanganate.—W. D. B.

*On the Valuation of Calcium Tartrate.* Dingl. Polytechn. Jour. 254 [12], 491.

ACCORDING to L. Weigert (*Zeitschrift für analytische Chemie*, 1884, S. 357), besides crude argol, also calcium tartrate now serves as raw material for the manufacture of tartaric acid compounds. In both cases the dealings are based on tartar-degrees—that is, the percentage of calcium tartrate contained is expressed in the equivalent quantity of potassium bitartrate. Thus 260 parts of crystallised calcium tartrate are equivalent to 188.11 parts of potassium bitartrate, or one tartar-degree is  $188.11 : 260 = 1.3821$  kilos. calcium tartrate in 100kilos. of the crude substance, whilst 1 per cent. of a kilogram. of (pure) calcium tartrate = 0.7235 of a tartar-degree (Weinstein-Grad). In order to estimate its technical value the calcium tartrate is decomposed by boiling with potassium carbonate into neutral potassium tartrate and calcium carbonate. After filtering off the residue the solution is evaporated and mixed with acetic acid to bring about the formation of potassium bitartrate, and this is washed with alcohol and titrated. At the same time the excess of potassium carbonate which is used should be as small as possible, the acetic acid also added only in corresponding excess, the washing sufficiently long continued, and the mixture of potassium carbonate and tartrate, after treatment with acetic acid, must still contain some water on treatment with alcohol in order to obtain exact results. The analytical details are as follows:—5grm. of powdered calcium tartrate are placed in a small flask with 30cc. of a 10 per cent. solution of potassium carbonate, and heated for one or two hours in a water bath. The flask itself becomes strongly attacked, but this is without influence on the result. The contents are filtered into a porcelain basin, and washing with hot water is continued until the washings cease to react on red litmus paper. The filtrate is evaporated in the porcelain basin on the water bath to about 5cc. (not to dryness). 5cc. strong acetic acid are now added and moved about in the dish so as to come in contact with every portion of the residue, and the whole is placed on a water bath for one or two minutes, as the acetic acid does not react quickly enough in the cold. 100cc. of 90 per cent. alcohol are now added and allowed to stand several hours. Then it is filtered and washed with about 100cc. of 80 per cent. to 90 per cent. alcohol until 10cc. of the washings, after dilution with twice the volume of water, require only one or two drops of standard potash for neutralisation. Such a standard potash solution is used as serves for estimations of acidity in wines, and of which 1cc. corresponds to 0.01grm. tartaric acid or 0.02508grm. potassium bitartrate. To the quantity of tartar found by the titration 0.0165grm. tartar is added as correction for the above quantities of liquids used, or, if 5grm. calcium tartrate is used, 0.33 per cent. tartar must be added. These corrections allow for the quantity of tartar remaining in the solutions, and are the mean of many estimations. In testing calcium tartrate for carbonate a titration is admissible, not on account of the difficulty of decomposition or the want of sensitiveness of the indicator, but on account of a remarkable displacement of the neutral point, occasioned by the impurities present in the crude calcium tartrate, the error sometimes being as much as 10 per cent. calcium

carbonate. The carbonic acid must therefore be evolved for estimation by weight or volume. Calcium tartrate is sometimes met with in commerce, which contains potassium bitartrate; this is especially the case, if, in the working up of the lees, too small a quantity of hydrochloric acid has been used. It is recognised that one part of hydrochloric acid ( $\text{HCl}$ ) is capable of dissolving 5.15 parts of potassium bitartrate, but this is only true for a boiling temperature. In the cold double that quantity is always necessary in order to keep the potassium salt in solution, otherwise a retrograde action takes place. If only so much hydrochloric acid has been added in the working up of the lees, as to keep the tartar dissolved whilst hot, some of the tartar separates out, part remaining in the cloths of the press, and part separating out when the solution is treated with the powdered chalk.—G. H. B.

**ERRATA.**—In February number of this Journal, on p. 107, col. 2, line 2 from top, after "thick," insert "tar." On p. 112, col. 1, lines 15 and 62 from top, and in col. 2, lines 11 and 15 from top, for "isabonaphtha," read "ssabonaphtha." On same page, col. 1, lines 1 and 2 from foot, omit the word "however."

## New Books.

**A PRACTICAL TREATISE ON THE RAW MATERIALS AND FABRICATION OF GLUE, GELATINE, GELATINE VENEERS AND FOILS, ISINGLASS, CEMENTS, PASTES, MUCILAGES, ETC., BASED UPON ACTUAL EXPERIENCE.** By F. DAWIDOWSKY. Translated from the German, with extensive additions, including a description of the most recent American processes, by WILLIAM T. BRANNT. Illustrated by thirty-five engravings. Philadelphia: Henry Carey, Baird & Co., Industrial Publishers, Booksellers, and Importers, 810, Walnut Street. London: Sampson, Low, Marston, Searle, and Rivington, Crown Buildings, 188, Fleet Street; 1884.

THIS is an 8vo volume, bound in cloth, and containing 284 pages of subject-matter, a table of contents, and a copious index. It is also illustrated with thirty-five engravings. The subdivisions of the table of contents, forming also the chapter headings, are as follows: I. What is Glue? II. Raw Materials and Manner of Preparing them for the Manufacture of Glue; III. Fabrication of Glue; IV. Plan and Arrangement of a Glue Factory; V. Gelatine and its Preparation; VI. Uses of Glue and Gelatine; VII. Different Varieties of Glue and Gelatine, and special directions for their preparation; VIII. Cements and Pastes; IX. Pastes and Mucilages; X. Present Status of the Fabrication of Glue.

**ALKALI TABLES FOR THE USE OF CHEMICAL MERCHANTS, MANUFACTURERS AND BROKERS.** By OSWIN BELL. Newcastle-on-Tyne: Boazman, Dickson & Co., 25, Quayside; 1885.

A small pamphlet measuring about  $3\frac{1}{2}$  by  $2\frac{1}{2}$  in., with paper cover; price 1s. The tables are arranged after the fashion of a ready reckoner, and are such as to enable one to see at once the value per ton from the value per unit per cwt., less various discounts.

**THE GAS MANAGER'S HANDBOOK**, consisting of Tables, Rules, and useful information for Gas Engineers, Managers, and others engaged in the Manufacture and Distribution of Coal-gas. By THOMAS NEWBIGGING, Memb. Inst. of Civil Engineers. Fourth Edition. Illustrated. London: Walter King, 11, Bolt Court, Fleet Street; 1885.

SMALL 8vo volume, handsomely bound in morocco leather and gilt, containing 382 pages of subject-

matter, tables of contents, and illustrations, of which the work contains 280, and a copious alphabetical index. The work contains concise but adequate information and practical data on the following heads:—Coal and Cannel; Retort-house, Retort-benches, Retorts and Mountings; Condensation and Condensers; Exhausters; Steam Boiler and Engine; Washers; Scrubbers; Bye-pass Mains and Valves; The Tar Well; Purification and Purifiers; Tests for Detection of Impurities; Station Meter House and Meter; Pressure Gauges; Pressure and Exhaust Registers; Gasholder Tanks; Gas-holders; Station Governor and District Governors; Main Pipes; Discharge of Gas, in cubic feet per hour, through pipes of various diameters and lengths, at different pressures; Service Pipes and Fittings; Public Lighting; Consumers' Gas Meters; Internal Fittings; Public Illuminations; Illuminating Power; Specific Gravity of Gas; The Use of Gas for Cooking, Heating, and Motive Power; The Residual Products; Coal Products; Chemical and other Memoranda; Sundry useful information relating to Gas Works, Gas Apparatus, Gas Manufacture and Supply; Miscellaneous; Office Memoranda; Epitome of Mensuration; Arithmetical and Algebraical Signs; Approximate Multipliers for facilitating Calculations; Table of Squares, Cubes, Square Roots, Cube Roots and Reciprocals of Numbers; Table of the Fourth and Fifth Powers of Numbers; Table of Diameters, Circumferences, and Areas of Circles, and Sides of Equal Squares; Weights and Measures, Decimal System.

## Monthly Patent List.

### ENGLISH APPLICATIONS.

1885.

#### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

- 2620 C. P. Scrimshire, Blacknave, Monmouthshire. A compound furnace. February 26  
 2642 J. H. Johnson, London. Improvements in filter presses. Communicated by F. Quarez and R. Quarez, France. Feb. 26  
 2652 J. Laidlaw, Glasgow. Improvements in centrifugal machines, otherwise known as hydro extractors. Complete specification. March 1  
 2664 J. Prince, London. Improvements in brick kilns, and in kilns for burning clay, china, earthenware, etc. March 6  
 2655 R. J. Friswell and A. Myall, London. Improvements in filter presses. March 9  
 2659 H. E. Newton. Improvements in materials for lining furnaces, crucibles, and similar apparatus. Communicated by J. E. Verdier, France. March 9  
 3133 J. Inray, London. An improved manufacture and application of materials for lining furnaces and metallurgical vessels or utensils. Communicated by H. Renuart and F. Vaton, France. March 10  
 3165 W. P. Thompson, Liverpool. Improvements in furnaces. Communicated by A. Backus, jun., United States. Complete specification. March 11  
 3267 P. Woodrow, Glasgow. A new or improved gas furnace for heating tubes. March 13  
 3280 M. Pass, London. A mill or apparatus for effecting at the same time the combined operations of drying and crushing or grinding, reducing, triturating, or amalgamating, applicable to the treatment of sulphate of lime, whitening, cement, guano, and other materials or substances. March 13  
 3361 A. G. Browning and F. G. Vivian, Llanelli. Improved roof settings. March 16  
 3418 R. M. McDouall, Glasgow. Insuring safety from collapse in stills or other close vessels. March 17

#### II.—FUEL, GAS, AND LIGHT.

- 2104 J. F. Braidwood, London. Improvements in means and apparatus for closing the mouths of gas retorts, applicable to other like purposes. February 21  
 2417 A new or improved torch and composition for same. Communicated by J. Dax, Germany. Complete specification. February 25  
 2489 G. Love, jun., London. Improvements in condensing apparatus for treating or purifying coal gas. February 24  
 2560 J. Barnett, London. Improvements in the use of artificial fuel. February 21  
 2793 J. A. Veadon, Leeds. Improvements in the manufacture of coke. February 25

- 2681 D. J. Blaikley, London. An apparatus for detecting the presence of coal or other gas in atmospheric air. February 27  
 2720 W. S. Oliver, London. Improvements in the manufacture of gas for heating and illuminating purposes. Feb. 28  
 2846 E. Davies, Liverpool. Improvements in obtaining or collecting gas for illuminating or heating purposes. March 4  
 2891 W. Potter, London. An improved method of and apparatus for heating, enriching, and consuming coal gas. March 4  
 2918 J. O. Spang, London. Improved means and apparatus connected with the production of gas for use with liquid fire-extinguishing chemicals. March 5  
 3325 T. Alexander, S. Alexander, and R. Paterson, Glasgow. Improvements in apparatus for making oil gas. March 11

#### III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, ETC.

- 2693 F. J. Rowan, Glasgow. Improvements in distilling and obtaining useful products from coal or other carbonaceous mineral, and in apparatus therefor. February 28  
 3285 A. W. L. Reddie, London. Improvements in the doors of coke furnaces. Communicated by C. Dahlmann, Germany. March 15

#### IV.—COLOURING MATTERS AND DYES.

- 3119 H. J. Haddan, Westminster. A manufacture of blue and violet colouring matters. Communicated by the Farben-fabriken vormals F. Bayer & Co., Germany. March 10

#### V.—TEXTILES, COTTON, WOOL, SILK, ETC.

- 2534 S. H. Sharp, Halifax. An improved means and method of making wool textile fibre. February 25  
 waterproof and acidproof. February 25  
 2556 J. C. Mewburn. Improvements in drying textile fabrics or other materials. Communicated by Picron and Dehailre, France. February 25  
 3086 W. Matlier, London. Apparatus for soaking, boiling, or dyeing textile materials, or subjecting them to the action of liquids or gases. Complete specification. March 10  
 3170 J. Scott, Dover. Scott's process for dry cleaning textile fabrics. March 11

#### VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

- 2380 T. Holliday, London. Improvements in the production of azo colours on textile fibre. February 25  
 3249 J. A. Ashwell, Liverpool. Improvements in the process of dyeing hosiery and other like goods, and in apparatus therefor. March 12

#### VII.—ACIDS, ALKALIS, AND SALTS.

- 2173 J. W. Kynaston, Liverpool. Improvements in the manufacture of sulphur from sulphureted hydrogen. Feb. 21  
 2178 W. Weldon, Burstow. Improvements in obtaining solid caustic soda from fused caustic soda. Communicated by A. R. Peehney et Cie., France. Complete specification. February 24  
 2578 H. Simon, London. Improvements in apparatus for the distillation of ammoniacal liquors, and for the treatment of the resulting ammoniacal vapours. Communicated by the Berlin Anhaltische Maschinenbau-Actien Gesellschaft, Germany. February 25  
 2645 J. O. Spang, London. Improved means and apparatus connected with the production of carbonic acid gas for extinguishing fire. February 25  
 2761 W. Weldon, Burstow. Improvements in the manufacture of caustic soda. March 2  
 2762 W. Weldon, Burstow. Improvements in and relating to the utilisation of the phosphoric acid of the slag of the basic steel process. Communicated by E. Lombard, France. March 2  
 3095 J. Wilson, Edinburgh. Improvements in decomposing liquors containing chloride of magnesium. March 10  
 3326 J. H. Wright, Liverpool. Improvements in the manufacture of chloride of ammonium. March 11

#### VIII.—GLASS, POTTERY, AND EARTHEN-WARE.

- 2330 E. M. Knight, Halifax. Improvements in blown glass bottles and in the moulds employed in the manufacture thereof. February 20  
 2340 E. M. Knight, Halifax. Improvements in blown glass taps and in moulds employed in the manufacture thereof. February 20  
 3143 G. J. Atkins, London. A new or improved process for the decoration and treatment of glass, porcelain, metal, and other surfaces. March 17

#### IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

- 2742 R. E. Goolden, London. The manufacture of improved plastic compounds. February 23

2775 W. J. A. Donald, London. Improvements in the manufacture of refractory materials and bricks and other fire-resisting articles suitable for lining furnaces and converters and for other uses. March 2

2806 J. Cawley, London. An improved mineral amalgam or cement. March 3

2886 W. Millar and C. F. Nichols, London. Improvements in the means of accelerating the setting and hardening of cements. Complete specification. March 4

2927 W. Millar and C. F. Nichols, London. A new or improved fibrous, fireproof, and waterproof composition for constructive, decorative, and other purposes. Complete specification. March 5

3097 J. Rust and H. J. Rust, London. An improved vitreous material for paving purposes. March 10

3139 F. Schiffer, London. An improved furnace or kiln for the production of cement or lime and for similar purposes. March 10

3251 G. M. Hammer and E. G. Hammer, London. Black or coloured plaster, cement, etc., for forming improved writing surfaces on walls, etc., of schools and class-rooms. March 12

## X.—METALLURGY, MINING, ETC.

2338 J. Giers, London. Improvements in means or apparatus for the treatment of steel ingots. Complete specification. February 29

2419 J. Edwards, G. W. Hannan, and F. H. Lyle, London. Improvements in dressing tin ores, and apparatus therefor. February 23

2833 A. W. L. Reddie. An improvement in the process of obtaining castings in steel or other metal. Communicated by G. L. Robert, France. February 26

2636 T. Gilmour, Glasgow. Improvements in casting steel. February 27

2840 D. and L. Roberts, Stockton-on-Tees. Improvements in furnaces and hearths or fireplaces for the refining of iron and steel, and also for the production of these metals. March 1

2877 F. Ellerhausen, London. Improvements in the extraction of metallic lead from sulphurous lead ores called galena. Communicated by S. Mayour, Spain. March 1

2973 W. E. Gedge, London. A new and improved process of precipitating lead from sulphurous lead ores. Communicated by F. Ellerhausen, Spain. March 6

3075 H. A. Nye and J. Whalley, London. Improvements in the construction of apparatus for desilvering lead; applicable also for lifting and transporting cements and other pulverulent substances, as also pulpy materials. March 9

3088 W. E. A. Hartmann, Swansea. Improvements in the electro-deposition of copper. March 10

3386 N. C. Cookson, Newcastle-on-Tyne. Improvements in smelting sulphide of antimony. March 15

3457 L. A. Groth, London. A new or improved method of manufacturing the chloride or double chloride with sodium or potassium of aluminium or glucinum (beryllium) in a dry state. Communicated by R. Gratzel, Germany. January 5. Previously included in No. 156

## XI.—FATS, OILS, AND SOAP MANUFACTURE.

2331 M. Ayrton, Halifax. Improvements in the production of white oil or grease from black oil or brown grease. February 21

2900 E. Green and E. Needham, Halifax. Improvements in the manufacture of washing and cleansing fluid. March 7

3101 F. V. Greene, London. An improved process for extracting oil and albuminous matter from maize and other grain. Complete specification. March 10

3111 C. R. Huxley, London. Ammoniated soaps, free from oleates, and compounded to dispense with the destructive friction of the brush. March 17

3419 F. O. Kloninger, London. Improvements in machinery for crushing and preparing fat for the refining operation. March 17

## XII.—PAINTS, VARNISHES, AND RESINS.

2754 J. W. Davies, London. Carbon black converting the refuse from prussiate of potash, alum, and other chemicals into black pigment, applicable for paint, japan, blacking, harness composition, india-rubber goods, engine packing, filters, and other purposes. March 2

2835 E. Uchiel and O. Muller, London. An improved anti-fouling composition. March 12

3112 W. Gibson, G. Wilson, and W. J. Clark, Great Driffield, Yorkshire. An improved composition for the prevention of corrosion or incrustation in steam boilers. March 16

## XIII.—TANNING, LEATHER, GLUE, AND SIZE.

2354 A. Anderson, Paris. An improved substitute for leather. February 21

2735 R. R. Gubbins, New Cross, and C. K. Farquharson, London. Improvements in manufacturing and water-proofing artificial leather. February 28

3105 L. Simpson and J. Davis, London. Improvements in tanning apparatus. Complete specification. March 10

3213 M. Kitchin, London. Improvements in the means or apparatus for dissolving materials used in tanning. March 12

## XV.—SUGAR, STARCH, GUM, ETC.

2329 J. Laidlaw, Glasgow. Improvements in the manufacture of sugar in apparatus therefor. February 20

2533 H. J. Chapin, London. Improvements in apparatus or devices for the treatment of sugar-cane. Complete specification. February 25

2724 C. D. Abel, London. Process for the purification and decoloration of saccharine liquors, juices, or syrups. Communicated by La Société Nouvelle de Mécaniques du Sucre de St. Louis, France. February 28

3050 W. P. Kelly, Graigue, Ireland. Improvements in the manufacture of starch from rice. March 9

3208 J. F. Gent, London. Products prepared from rice. Complete specification. March 11

## XVI.—BREWING, WINES, SPIRITS, ETC.

2102 J. R. Sharpe, London. An improved aerated beverage, to be hereafter known as "Sarine," and the method of preparing the same. Complete specification. February 21

2748 J. Death, jun., Cheshunt. Improvements in preparing and drying grain and gelatinised grain for use in brewing, and apparatus in connection therewith. March 2

3193 A. Behr, London. Apparatus and process for producing malt. Complete specification. March 11

3357 J. Imray, London. Manufacture of pressed yeast Communicated by M. Hatschek, Switzerland. March 19

## XVII.—FOOD PRESERVING, MEATS, ETC.

2403 W. G. Gard, London. Improvements in preserving or curing flesh and fish. February 21

3544 G. Jeffs, Great Grimsby. Preserving fish in a fresh condition. March 19

## XVIII.—SANITARY CHEMISTRY, DISINFECTANTS, ETC.

2332 J. G. Lorrain, London. Improvements in the filtration and purification of fluids, and in the oxidation of matters suspended or dissolved therein. February 21

2728 C. Price and H. Cleave, London. Improvements in the filtration of sewage, and in apparatus therefor. February 23

2739 J. C. Stevenson, London. Improvements in disinfectants. February 23

2865 G. H. Lloyd, London. Improved means and apparatus for producing transparent ice. March 1

2885 W. F. B. M. Mainwaring and J. Edmunds, London. Improvements in the treatment and purification of sewage and water containing organic matter. March 1

3172 W. D. Curzon and G. S. Jones, London. Improvements in the treatment and utilisation of sewage sludge. March 11

## XIX.—PAPER, PASTEBOARD, ETC.

2722 C. D. Abel, London. An improved manufacture of safety paper for cheques and similar purposes. Communicated by the Patent Papier Fabrik zu Penig, Germany. February 28

2723 C. D. Abel, London. An improved manufacture of safety paper for cheques and similar purposes. Communicated by the Patent Papier Fabrik zu Penig, Germany. February 28

3009 W. H. Richardson and W. Bertram, Glasgow. Improvements in the manufacture of paper pulp, and in the apparatus or mechanism used therefor. March 7

## XXI.—EXPLOSIVES, MATCHES, ETC.

2991 C. Dixon, Birmingham. Improvements in charges and cartridges to be used with certain kinds of powder for small arms and for other purposes. March 7

3152 G. E. G. Simons, Merthyr Tydvil. Non-inflammable explosives. March 11

## ENGLISH PATENTS PUBLISHED.\*

APPLIED FOR DURING 1884.

### I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

3232 (1873, Reprint) E. Voisin. Cupola furnaces. 6d

3188 H. Wedekind. Kilns for burning bricks or other analogous articles. Communicated by H. Dueberg. 6d

6342 J. Woods. Heating kilns, muffles, ovens, etc., and bricks, slabs, or blocks to be used therein. 10d

6513 J. H. Johnson. Furnaces for burning liquid hydrocarbons. Communicated by J. Buffet. 6d

\*Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lusk, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 5d.	4d
Above 5d., and not exceeding 1s. 5d.	1d
" 1s. 5d. " " 2s. 4d.	1d
" 2s. 4d. " " 3s. 4d.	2d

6565 J. G. Wilson. Improvements in crucibles and means vessels for melting, refining, or converting metals, and means for heating same. Communicated by J. E. Bott. 6d  
7236 G. King. Fastenings for retort lids. 6d  
7371 T. Knott. Furnaces. 6d

## II.—FUEL, GAS, AND LIGHT.

3766 H. H. Hazard. Condensation and absorption of the products of combustion from coal or other gas or oil used either for lighting or heating purposes. 6d  
5932 R. Irvine. Improvement in the distillation of coal in the manufacture of coal gas for the subsequent purification of the said gas. 2d  
6094 W. Young and G. T. Beilby. Distillation of mineral oils, and apparatus therefor. 1s 2d  
6553 A. C. Henderson. Method and apparatus for manufacturing carburetted hydrogen gas for lighting or heating. Communicated by C. Wilhelm. 6d  
6631 M. Schwab. Apparatus for making illuminating gas. Communicated by J. Overholt. 6d  
6983 A. P. Price. Purification of coal gas, or other gases containing ammonia or ammoniacal compounds. 4d  
8409 W. Young and G. T. Beilby. Distillation of mineral oils, etc. 10d  
8579 J. E. Walsh. Furnaces and retorts for the manufacture of gas. Communicated by A. Ryex. Amended specification. 8s  
13580 H. H. Lake. Extraction of paraffin or other solid substance from oil or other liquid, and apparatus therefor. Communicated by R. H. Smith. United States. 6d  
11198 H. G. Fairburn. Machinery for washing, separating, and purifying coal and other substances. 4d

## IV.—COLOURING MATTERS AND DYES.

5512 J. H. Johnson. Preparation of yellow colouring matters from tetramethylidiamidobenzophenone and analogous ketone bases or their halogen derivatives. Communicated by the Badische Anilin- und Soda-Fabrik. 4d  
7067 J. Wetter. Producing betanaphthol-disulpho-acids, separating the same, and obtaining colouring matters therefrom. Communicated by the Leipziger Anilin-fabrik, Beyer and Kegeel. 4d  
7095 J. Wetter. Separating the different betanaphthol-monosulpho-acids from a mixture of the same, and obtaining colouring matters therefrom. Communicated by Beyer and Kegeel. 4d  
15456 W. E. Gedge. Method of preparing alizarin and other anthracene colouring substances. Communicated by G. Jagenburg and C. Leverkus & Sons. 2d

## VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

11231 J. P. Delahanty. Dyeing garments, etc. 6d  
1885.  
471 W. Mather. A process for bleaching webbs or yarns of vegetable textile materials. 2d  
657 G. Kassner. Improvements in the process of bleaching. 2d

## VII.—ACIDS, ALKALIS, AND SALTS.

3723 W. L. Wise. Manufacture of salicylic acids. Communicated by Chemische Fabrik, vormals Hofmann und Schoetensck, Germany. 2d  
5973 J. Wilson. Manufacture of chlorate of potash. 4d  
6022 E. F. Trachsel. Producing oxide and carbonate of strontium, of barium, or of calcium, and obtaining by-products therefrom. 4d  
6051 W. V. Wilson and J. Storey. Production of compounds containing nitro-cellulose. 4d  
6179 J. Mangnall and R. S. Lloyd. Generating carbonic acid gas, and apparatus therefor. 6d  
6215 W. L. Thompson. Purifying sulphuric acid, and recovering the arsenic contained therein. Communicated by G. Thomson and W. Kemp. 4d  
6290 G. Rosenthal. Manufacture of alumina and potash alum. 4d  
6367 S. Gilchrist Thomas. Manufacture of sodium. 2d  
6461 W. V. Wilson. Manufacture of lead salts, for application to the manufacture of white lead. 6d  
6734 W. J. A. Donald. Manufacture of chromates and bichromates. 2d

## VIII.—GLASS, POTTERY, AND EARTHENWARE.

6399 J. H. Johnson. Manufacture of white opaque glass, and enamel. Communicated by — Tedesco. 4d  
15945 W. H. Lake. An improved compound to be used as a substitute for ivory. Communicated by J. B. Edson, United States. 4d

## IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

6157 F. Ransome. Manufacture of cement. 4d  
7395 J. A. Jones. Concrete or artificial stone for paving or other purposes. 2d  
7397 J. A. Jones. Concrete or artificial stone for paving or other purposes. 2d

## X.—METALLURGY, MINING, ETC.

5245 T. Slater. Manufacture of alloys of chromium, and utilisation thereof in the coating of metallic surfaces. 4d  
6371 D. G. Fitzgerald. Refining gold and silver. 4d  
6193 H. H. Lake. Compound metal or alloy for deacidising and coating metal plates. Communicated by J. Benbow Jones. 4d  
6722 A. P. Price. Obtaining copper. 2d  
7257 J. Beasley. Manufacture of iron and furnace linings to be used by said manufacture. 4d  
7940 A. M. Clark. Process of treating iron. Communicated by R. B. Abbott. 4d  
11690 F. J. Brougham. Process of and means for equalising the temperature in cast-steel ingots. Communicated by A. Sailer. 6d

## XI.—FATS, OILS, AND SOAP MANUFACTURE.

6271 E. Sonstadt. Manufacture of soaps, dentifrices, and other detergent substances. 2d  
6185 W. P. Thompson. Bleaching or purifying dark-coloured mineral and other distillable oils. 6d  
11681 C. R. A. Wright. Improvements in the manufacture of soap. 4d

## XII.—PAINTS, VARNISHES, AND RESINS.

2630 A. Gernot and L. Riviere. Treating certain resins for obtaining a new elastic substance. 4d  
5192 J. C. Martin. Manufacture of red pigments or paints. 2d  
6036 E. Metcalf. Preserving and preventing incrustation in steam boilers. "The new anti-corrosive preparation." 2d  
1885.  
3 S. R. Hooper. Improvements in the manufacture of euphorbia paints. 2d

## XIII.—TANNING, LEATHER, GLUE, AND SIZE.

3375 J. Salamon. Process of tanning hides or skins. Communicated by L. Vergez. 4d

## XV.—SUGAR, STARCH, GUM, ETC.

7199 J. Jeyes. Manufacture of elastic compounds. 4d  
7235 V. Daix and A. L. Passoz. Extraction of sugar from molasses and other saccharine products. 4d  
15150 J. J. C. Smith. Manufacture of rubber compositions. 4d  
11092 G. W. Parbury. Process and apparatus for treating megass for extracting sugar therefrom. Communicated by G. Kottmann. 4d

## XVI.—BREWING, WINES, SPIRITS, ETC.

1945 J. McFarlane. Stirring apparatus for mash tuns, etc. 6d  
5096 F. S. Barff. Treatment of liquids and substances which are subject to fermentation. 2d  
5747 W. Aubert. Preserving Lager beer. 4d  
6361 J. A. Meylers. Treatment of locust beans for the purpose of preparing beverages therefrom. 2d  
6557 G. Epstein. Treatment of grain or other materials for the production of alcohol therefrom. 6d  
1885.  
46 P. Platt and J. M. Aitchison. Kilns for drying malt, hops, etc. 4d

## XVII.—FOOD PRESERVING, MEATS, ETC.

6301 E. Sonstadt. Preparation of salt, saltpetre, sugar, and other antiseptic substances for use in the preservation of food. 2d  
16700 M. Bauer. Improvements in the manufacture of meat powder. 2d  
16701 M. Bauer. The manufacture of preserved meat and vegetables. 2d

## XVIII.—SANITARY CHEMISTRY, DISINFECTANTS, ETC.

3125 (1876, Reprint) A. Fryer. Treating refuse, etc. 6d  
5496 (1883, Amended) W. Anderson. Purification of water. 6d  
6414 W. P. Thompson. Utilization of human excreta, etc. Communicated by — Bryden. 10d  
7255 M. Williams. Preparing lime for sanitary purposes. 2d  
13282 A. F. Smith. A material in a granulated form for the purpose of filtering sewage and other fluid matter. 2d  
17041 A. J. Marquand, E. Hancock, and J. R. Powell. Prevention of corrosion and removing of deposit in steam or other boilers. 4d

## XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

6904 N. A. Helouis. Manufacturing light essences by the distillation of coal, wood, turf, oil, and other similar substances. 8d

## XXI.—EXPLOSIVES, MATCHES, ETC.

7299 E. de Pass. Railway detonating signals, etc. Communicated by Lirand and Gaupillat. 6d

## NOTICES.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those members of Council whose names are placed in italics in the annexed list, will retire from their respective offices at the forthcoming Annual General Meeting.

Mr. Edmund K. Muspratt has been nominated to the office of President, and Dr. W. H. Perkin, F.R.S., has been nominated Vice-President under Rule 11.

Mr. I. Lowthian Bell, F.R.S., Dr. Peter Griess, F.R.S., Mr. John Spiller, and Mr. E. C. C. Stanford have been nominated Vice-Presidents under the provisions of Rule 8; and Sir Bernhard Samuelson, Bart., M.P., and Dr. S. A. Sadler have been nominated ordinary members of Council in the place of Dr. Peter Griess, F.R.S., and Mr. John Spiller, nominated Vice-Presidents under the provisions of Rule 17.

The Treasurer and Foreign Secretary have been nominated for re-election.

Members are hereby invited to nominate fit and proper persons to fill the four vacancies thus created among the ordinary members of Council, in accordance with the provisions of Rule 18. Nomination forms for this purpose can be obtained from the General Secretary upon application.

Members are hereby informed that the Annual General Meeting (1885) will take place in London in the second week in July. Details and arrangements will be published in due course, and members will receive their tickets of membership, which, as heretofore, will form vouchers in visiting works and places of interest.

Authors of papers printed in the Journal are hereby notified of the fact that, in accordance with Bye-law 43, they are entitled to receive not more than 50 gratuitous copies of their papers. Authors should state on their manuscripts their desire to have free copies, adding the number wished for. Unless the contrary be specially desired, this being stated on the manuscript, the reprints of an author's paper will not include the report of any discussion that may have arisen after the reading of the paper.

Members are hereby advised that the Subscription for 1885 falls due at the beginning of the year, and should be paid as soon afterwards as possible. The Council has decided that after January 1st, 1885, the 29th Bye-law will be strictly enforced, so that Members whose subscriptions are more than four months in arrear, will not continue to receive the Society's Journal.

Inquiries having been made as to the transactions of the Newcastle Chemical Society, the Committee of the Newcastle Section have to state that a very few complete sets are remaining, and will be sold to members at £2 10s. per set. A number of separate volumes can also be had by members wishing to complete their sets, at 10s. per volume (generally three years' issue). Application for these should be made to the Local Secretary of the Newcastle Section.

## LIST OF MEMBERS ELECTED APRIL 23rd, 1885.

Chas. A. Blake, 17, Piccadilly, London, W., pharmacist.  
 J. H. Bury, Church Chemical Works, near Accrington, chemical lecturer.  
 Samuel Butler, Compton, Wolverhampton.  
 J. G. Carruthers, Burnbrae House, Milngavie, N.B., assistant manager of dye works.  
 Thos. Coomber, 3, Osborne Road, Clifton, Bristol, chemical manufacturer.  
 John Craw, Caledonia House, Paisley, N.B., dyer.  
 Chas. J. Ellis, 7, Hillhead Gardens, Glasgow, assistant professor technical chemistry.  
 M. W. Dunncombe, St. Augustine's Parade, Bristol, manufacturing optician.  
 H. M. Frear, 49, Osborne Road, Tollington Park, N., analyst.  
 Jas. M. Glen, Ferencze Printworks, Barrhead, N.B., calico printer.  
 A. H. Holditch, Wigan Coal and Iron Co., Ltd., Wigan, analyst.  
 Albert H. Hunter, Beech House, Pendleton, Manchester, technical chemist.  
 W. Arthur Jones, Kenwith Lodge, Redland, Bristol, soap manufacturer.  
 W. Kershaw, Victoria Terrace, Wheelton, near Chorley, bleacher.  
 J. N. Larned, Young Men's Library, Buffalo, N.Y., U.S.A., superintendent.  
 Arthur J. Lawson, Marsh Soap Works, Bristol.  
 Jas. Lemon, M. Inst. C.E., Palace Chambers, Westminster, S.W.  
 Wm. Lester, Bron Offa, Wrexham, North Wales, lime manufacturer.  
 Oscar Lowman, Polytechnicum, Charlottenburg, Berlin, student.  
 A. Mumford, 9, Westwell Street, Plymouth, Devon, manager chemical works.  
 C. W. Cope Proctor, Heathercliffe, Clifton Down, Bristol, agricultural chemist.  
 L. Trant O'Shea, Firth College, Sheffield, assistant lecturer on chemistry.  
 H. C. Pearson, 6, Woodland Grove, Colwick Vale, Notts., bleacher.  
 A. J. Rawlinson, Newton-le-Willows, Lancashire, manager manure works.  
 Jos. Redfern, 19, Harvie Street, Bridgeton, Glasgow, manufacturing chemist.  
 Chas. F. Richardson, The Elms, Newark-on-Trent, brewer and maltster.  
 John Robertson, Mosswell, Milngavie, near Glasgow, calico printer.  
 Stephen Sellon, 17, Scarsdale Villas, Kensington, civil engineer.  
 J. E. L. Shadwell, Meadowbank, Melksham, Wilts., chemist.  
 Fred. Smith, 16, Oakley Crescent, Chelsea, S.W., science student.  
 W. J. Stevens, 8, Cromwell Terrace, Totterdown, Bristol, technical chemist.  
 W. J. Taylor, 35, Forsyth Street, Greenock, N.B., science student.  
 C. B. Telfeisen, 9, Nelson Street, Bristol, dry soap manufacturer.  
 Eugene F. Trachsel, 41, Victoria Terrace, Ncath, South Wales.  
 Wm. Weston, H.M. Dockyard, Portsmouth, Admiralty chemist.  
 Jos. Wethered, The Avenue, Clifton, Bristol, colliery owner.  
 S. D. Wills, Castle Green Colour Works, Bristol, varnish manufacturer.  
 W. H. Wilson, Presidency College, Madras, and Roy. School of Mines, South Kensington, lecturer on physics.  
 J. H. Woodward, Houlton Street, Bristol, vinegar manufacturer.  
 A. C. Young, 61, Tyrrwhit Road, St. John's, S.E.  
 Robert Young, 3, Radstock Road, Fairfield, Liverpool, technical chemist.  
 Jas. H. Young, Dalmaecoulter Works, near Airdrie, N.B., manager.

## CHANGES OF ADDRESS.

W. H. Aubrey (d/o St. John's), Caledonia Estate, Province Wellesley, Penang.  
 W. S. Curphey (d/o Partick), 268, Renfrew Street, Glasgow.  
 A. S. Elmore (d/o Blackfriars Road), Ionian House, 339, Clapham Road, S.W.  
 Henry Gall (d/o Salindres), Directeur, L'Usine de Produits Chimiques de Villers par Hermes, Oise, France.  
 Jno. A. Hall (d/o Harpurhey), 128, Lloyd Street, Greenheys, Manchester.  
 W. E. Hicks (d/o Manchester), 55, Shakespeare Street, Chorlton-on-Medlock, Manchester.  
 E. Hunter (d/o Goolle), 3, Park Terrace, Whitby.  
 W. Lane, jun. (d/o Adelaide Place), Southgate Brewery, Cork.  
 H. C. Lee (d/o Westminster), c/o Johnson & Co., Limited, brewers, Canterbury.  
 J. G. Lorrain (d/o Doctor's Commons), 3, Vernon Chambers, Southampton Row, W.C.  
 Frank E. Lott, The Laboratory, Bridge Chambers, Burton-on-Trent.

A. Macalister (d/o Clyde Chemical Works), Eastfield Chemical Works, Rutherglen, near Glasgow.  
 R. F. Macfarlane (d/o Portugal), 31, Dixon Avenue, Crosshill, Glasgow.  
 G. H. Makins (d/o Blackheath), Danesfield, Upper Lattimore Road, St. Albans.

MEETINGS, SESSION 1885—First Monday in each month (unless otherwise indicated).

May 1.—Messrs. Giles and Shearer—"The Real Strength of Aqueous Solutions of Sulphurous Acid."  
 Messrs. C. Napier, Blake, and Mook—"The Stassfurt Salts Industry, and its bearing on other Industries."  
 Discussion on Professor Munro's paper published in January number of the Journal, "On the Manorial Value of Filter-Pressed Sewage Sludge," read January 5.  
 June 1.—Messrs. Salamon and W. de Vere Mathew—"The Influence of Phosphates upon Fermenting Worts." Mr. H. B. Yardley—"Additional Note on Alumina in Superphosphate."  
 July.—The Annual General Meeting.  
 Notices of papers and communications for the meetings to be sent to the Local Secretary.

Meeting held April 13, 1885.

## FURTHER NOTES ON THE RADIAL PHOTOMETER AND THE PROPOSED STANDARDS OF LIGHT.

BY W. J. DIBDIN, F.I.C., F.C.S.

Chemist, and Superintending Gas Examiner to the Metropolitan Board of Works.

ONE of the first points which it is desirable to make clear, with regard to the use of the Radial Photometer

is the certainty attending the use of the instrument when the disc is arranged for equal angles of incidence of the rays from the standard and the light under examination. For the purpose of determining this question, I have made tests of the horizontal rays, with the disc in various positions—viz., vertical and inclined  $22^\circ$  and  $45^\circ$  in either direction, with the result that the readings obtained were perfectly concordant. It may, therefore, be assumed that the tests of rays, at angles above and below the horizontal, are correct when the screen is adjusted as I have directed. It is necessary that care should be taken to avoid errors due to reflection.

In the paper which I had the honour to submit to the Society last year, I drew attention to the difference in the quantity of light emitted from the broad part of flat flames, and from their edges. This question has since engaged my attention. I have made determinations of the quantity of light afforded in all directions horizontally by three classes of flames, testing them at every  $10^\circ$ . The results are stated in Table I. The diagrams show at a glance the positions in which the maximum light is thrown.

The value of the radial photometer is most strikingly shown in the examination of burners shaded by globes, reflectors, &c. For this purpose I have tested three Argand burners, fitted with different forms of shades. Table III. contains the results, which I have also put in diagram form. Two of these sets of observations clearly indicate that the form of the porcelain cup might be arranged to yield more satisfactory results, but considering the want of a suitable method of testing, before the radial photometer was introduced, there is little room for complaint. The effect of the well-known glazed-paper shade is very striking, the even distribution of light downward being very satisfactory. The tests of a Christinia burner, with and without its globe, are also interesting; but, as in this case the globe has to do the double duty of regulating the draught and reflecting the rays in a downward direction, it is difficult to see how its form can be improved. The tests of a new form of reflector well illustrate the character of the work of which the radial is capable. The tests may be taken at every degree where necessary, and thus most valuable comparative results obtained.

These instances might be multiplied almost indefinitely, but I do not think that more are required to point out the extensive range of work which this photometer renders possible. Further practice has shown that tests are easily and rapidly made, and that it is equally applicable for all classes of photometrical experiments.

The effect of a suitable reflector in diffusing the power of the light in particular directions is very marked, so much so, that in future competitive tests of burners and apparatus relating thereto, it would be highly desirable to make special awards for the best form and diffusing power of reflectors. In my judgment the most perfect reflector should throw the rays of light in such a manner as to evenly illuminate a level surface comprised within a circle whose circumference includes those rays falling at an angle of  $30^\circ$  below the horizontal.

The nearest approximation to this definition is the result given by the well-known porcelain shade supplied with Argand burners. When the cup is in position the rays, falling at all angles from  $0^\circ$  to  $60^\circ$  below the horizontal, are intercepted to an excessive extent. The importance of facility in testing a new disc for photometric readings is generally acknowledged. The form of carrier used with the radial photometer is especially adapted for readily adjusting the disc, so that either side may be turned towards

the standard light. It is only necessary to loosen the screw holding the carrier when the latter can be rotated on its axis. I propose to use this form of disc carrier, which reverses the mirrors as well as the disc, in the photometers at the gas-testing stations of the Metropolis under my charge, and have obtained the sanction of the Gas Referees to the change, which, I feel certain, will be a decided advantage.

#### THE PROPOSED STANDARDS OF LIGHT.

Amongst the numerous proposals for obtaining a light of constant illuminating power, the most varied substances are to be found; in fact, hardly a combustible material seems to be omitted from the list. It is unnecessary to recapitulate them further than to call attention to those which have been found, after repeated and lengthy trials, to afford ground for the hope that amongst them may be one which will eventually prove to be reliable under all circumstances. These are six in number—viz., candles; Carcel and Keates' lamps; Harcourt's pentane or air-gas flame; Methven's screened Argand flame; and Suggs' "Ten-candle Test." The combustibles employed with these are sperm, sperm and colza oils, pentane, and coal-gas both with and without pentane.

I need hardly mention that the only legal standard in this country is the sperm candle of six to the pound, each consuming 120 grains of sperm per hour, and that the Carcel is the legal standard in France. This lamp should consume 42gm. of colza oil per hour, at which rate it yields an average light equal to 9.5 average English candles. I have obtained this figure from the results of tests made in 1870, by Mr. Suggs, when he found it to be equal to 9.6 candles, and the mean of several series of tests which I have recently made, when I compared it with both Mr. Harcourt's pentane flame, and the Keates lamp, the average result being that the Carcel lamp was equal to 9.41 candles. If it is assumed, therefore, to be equal to 9.5 candles, it is certain that that assumption will not be far from the truth.

The attention which has been paid to the important subject of the standard of light during the past few years has resulted in three separate investigations being made. The first of these was in 1880 and 1881, when the Board of Trade appointed a committee, consisting of Drs. Williamson and Odling, and Mr. G. Livesey, to examine "the Standards at present in use for estimating the Illuminating Power of Coal-Gas, and of the Standards which have been proposed by Mr. A. G. Vernon Harcourt, Mr. T. W. Keates, and Mr. J. Methven." The report of this committee was very unfavourable to candles, Keates' lamp, and Methven's screen, but decidedly in favour of Mr. Harcourt's air-gas flame.

In 1883, the Gas Institute appointed a committee to examine the candles, Mr. Harcourt's air-gas flame, Mr. Methven's screen, and M. Giroud's "Verificateur," and "Relative" standard. This committee engaged the services of Messrs. Heisch and Hartley to conduct the experiments, and these gentlemen reported strongly in favour of the Methven screen, and as strongly against the Harcourt air-gas. During the past winter I have had an opportunity of making further examinations of the various proposed standards, and have submitted the results obtained, up to the present, to a committee of the Metropolitan Board of Works in the form of a report. I have not yet furnished my investigations, and hope to extend the number of tests and manner of making them very considerably. So far as my work has gone, I am of opinion that the public has now before it several propositions of a most promising character. I have found

that Mr. Harcourt's air-gas standard is very satisfactory in its results, and is easy to work. In this matter I regret to find that I am in direct opposition to the strongly-expressed opinions of the two eminent photometrists who reported to the Gas Institute committee so unfavourably of the pentane. I also found that the Keates lamp is thoroughly reliable, and of a most satisfactory character in every respect. The Methven screen gave very contradictory results, but I am willing to believe that these were in some degree probably due to two things: 1st, the too hurried use of the burner after lighting; and, 2nd, variations in

fact affords an explanation of the decrease in the quantity of light emitted through the Methven slot when the flame produced by carburetted gas is too high. The lower portion of the flame is brought nearer to the slot, which is thus opposed to a light of diminished intensity. So far as my tests have extended, I find that the "Ten-candle Test," when burning enriched gas, is remarkably constant, and well merits further trial.

Summing up the general results of the tests which I have lately made, and expressing them, for convenience, in percentage variation from the mean, I

ANGULAR RAYS.

the height of the flame. I found this latter to be a most important point when the carburetted gas was used, in place of the plain coal-gas. I confess to being disappointed with the Methven arrangement. I expected variations of a kind, but I was not prepared for some of the extraordinary results which were obtained. I am anxious not to do Mr. Methven an injustice, and am content, especially after the strongly expressed opinions of Messrs. Heisch and Hartley, to await the results of further tests, and in the meantime distrust myself, before finally rejecting a proposal which has met with such strong support. I have made some careful tests of a new form of standard introduced by Messrs. Sugg & Co., and called by them the "Ten-candle Test." As submitted it was arranged to burn common coal-gas of various qualities. The inventors do not claim that the light emitted is of constant quality when gases of various illuminating power are used; but, on the contrary, furnish a table of corrections for the particular gas employed. The limited number of tests which I have made with the arrangement has not impressed me favourably with the idea of using ordinary coal-gas as a standard combustible in this case more than with the Methven. I therefore tried the expedient of burning coal-gas enriched with the vapour of pentane. To my surprise I found that the quantity of light emitted by the system, when this rich gas was used, remained precisely the same as when the uncarburetted gas was employed—viz., 10 candles. This result was due to the fact that when the rich gas was employed, a greater portion of "blue" flame is obtained, which compensates for the increased quantity of light emitted by the portion of the flame utilised. This

find that the variations in the proposed standards were as follows—viz.:

### PERCENTAGE OF TESTS WITHIN ONE PER CENT. OF THE MEAN.

CANDLES. Tests by different operators .....	137
CARCEL LAMP. Tests with two lamps .....	390
KEATES' LAMP. Tests made with various lamps, oils, and wicks .....	710
Tests with one lamp, for constancy, Series No. 1 .....	684

METHVEN'S SCREEN. Tests made with "plain" and "carburetted" gas .....	370
Tests by different operators .....	125
SCGGS' "TEN-CANDLE TEST." Tests with "plain" and "carburetted" 167 candle-gas, and 112 candle-gas carburetted (eight tests only) .....	1000

The objections to the above standards may be summarised thus:—

*Candles.*—Variability of composition and melting point of sperm, and of the number and size of threads.

*Carcel Lamp.*—Quality of oil employed. Uncertainty of height of wick and glass, and of composition of wick.

*Keates' Lamp.*—Time required to produce flame, and uncertainty attending the use of a wick.

*Pentane.*—Attention and skill required; sluggish and unstable character of flame; effect of vibration of room; difficulty of reading.

*Methven's Screen.*—Quality of gas used with "plain gas" screen. Uncertainty of height of flame, especially when carburetted gas is employed.

*Supps' Ten-candle Test.*—Quality of "plain" gas used.

The replies to these objections are:—

*Candles.*—None.

*Carcel Lamp.*—Admitted.

*Kates' Lamp.*—The time is about thirty minutes, or little more than that required with any other of the proposed standards. With this lamp there is no uncertainty as regards the wick.

*Harcourt's Pentane.*—When the apparatus is properly arranged the attention required is so little as to be of no moment. The flame is perfectly steady in the absence of draught, or excessive movement of disc carrier. Accidental vibration of room does not affect it, and that the difficulty of reading the photometer disc is overcome by practice.

the possibility of an opponent having good grounds for his assertions, or that the difficulties of the case are so great as to preclude one person using more than one system to the best advantage. The fact is that photometry is by no means a "two-foot rule" science. Nothing can exercise the patience of an operator more than prolonged observations of this character. Unremitting care and minute attention to numerous details are absolutely necessary for the attainment of accurate results. It is therefore not difficult to imagine that an operator intimately acquainted with all the peculiarities of a given standard should be liable to obtain more constant results with that than with another with which he may be less accustomed. The constant transition from one standard to another, each differing in every

*Mithen's Screen.*—When "plain gas" having an illuminating power between 14 and 22 candles is used, the light passing through the slot is constant, and can be checked by the use of enriched gas, and a smaller slot. The height of the flame is easily controlled.

*Supps' Ten-candle Test.*—Variations in the quality of the gas employed do not affect the result, as correction is made for any increase or decrease in its illuminating power.

We have thus the present position of the standard of light controversy clearly defined. The conflict of testimony is so diametrically opposed that an outsider would naturally consider that either there is little disposition on the part of various advocates to admit

particular, and of varying luminosity, is most trying. These considerations show that great caution is necessary in arriving at a judgment on the whole question, which should be approached with due regard to the opinions and experiences of others.

I have spoken previously in favour of a high-power standard, and I see no reason to alter that view, although I gladly admit the facility with which readings were made when the pentane air-gas was employed during my recent experiments. With practice and great care the results are satisfactory, but they cannot, in my judgment, be obtained with the same facility and comfort to the observer as

when a higher power standard, such as the "Tencandle Test," or Keates' lamp, is used.

It is highly desirable that the standard combustible

liability to error; moreover, a standard of light should be self-contained, and available under all conditions. Circumstances will arise in which coal gas may not

employed should be of a definite character. For this reason I do not think that plain coal-gas is admissible. Its constant variation must be a source of frequent

be attainable. Many authorities seem to overlook this fact, and speak of a standard of light as if it was solely desired for the purpose of gas testing. I prefer

to put the question on a higher footing, and to consider that it should be looked at from all points of view. I therefore eliminate coal-gas from the list of sperm oil. The pentane may be used in two forms, either as proposed by Mr. Harcourt, or as proposed by Mr. Methven. In the first instance, Mr.

ANGULAR RAYS.

THE SAME BURNER WITHOUT REFLECTOR.

desirable standard combustibles. Under these circumstances I submit that the only combustibles of a reliable character now in question are pentane and Harcourt, to whom the credit of the introduction of pentane as a standard combustible is due, uses it in the most economical manner, every particle of the

substance being made to do effective work. In the second instance Mr. Methven uses it in a most extravagant form, utilising only a very small portion of the quantity actually employed. If used with the "Ten-candle Test" of Mr. Sugg, as I have suggested, it would be consumed nearly as rapidly as in Mr. Methven's arrangement, but nearly the whole of it could be made to do effective work. The sperm oil can only be used in the manner proposed by the late Mr. Keates.

These considerations, if generally accepted, narrow the question materially, and so afford hope that the day is not far distant when all differences will be reconciled, and one system universally adopted.

Before the question is finally settled, it is most sincerely to be hoped that the recommendation of the Congress of Electricians, which met in Paris in 1881, will be acted upon in some form, and the question made international. The matter has been under the consideration of a committee appointed by the British Association, but up to the present their efforts do not appear to have met with much success.

The following extracts from M. Monnier's "*Étude sur les Étalons Photométriques*" form such a valuable contribution to the subject, that I feel that little apology is needed for introducing them here:—

"On summing up the preceding determinations, one sees that one normal English candle consuming 120gr. of spermaceti per hour is equal to 0.120 normal carcel. One normal German candle of paraffin, of which the flame is 50mm. in height, is equal to 0.34 carcel. One normal candle of Munich consuming 10.4grm. of stearine per hour is equal to 0.153 carcel. One 'star' candle of five to the packet, consuming 10grm. of stearine per hour, and giving a flame of 52.5 millimetres, is equal to 0.136 carcel. One 'star' candle of six to the packet, under the same conditions, is equal to 0.132 carcel. The value of the normal carcel consuming 42grm. of oil per hour is therefore equal to 8.3 English spermaceti candles; 7.5 German paraffin candles; 6.5 Munich stearine candles; 7.4 'star' stearine candles of five to the packet; 7.6 'star' stearine candles of six to the packet. The gas of which 105 litres equals one carcel is equal to 13.2 candles by the English system, and to 14.5 candles by that of Berlin.

"We need not insist on the difficulties that one meets with when comparing the results of first experiments with such variable units, more than on the uncertainty which is attached to the relative value of different standards of light.

"One sees that the system proposed by Mr. Harcourt for representing a luminous standard constitutes an interesting progress towards photometrical measurements, and if the principle of this method were generally adopted, it would be easy to establish experimentally a standard burner representing a definite power of light. This we have done for the use of the laboratory by regulating the burner to a tenth of a carcel, in order to simplify the calculations. But as it would be very important that a work of this nature, for its conclusion, should have the unification of photometric measures, it is to be desired that the experiments to be made in this direction should be undertaken with the assistance of experts who have specially devoted themselves to this question in England and Germany, as well as in France. We should perhaps in this way arrive at the realisation of an international standard of light, the use of which would permit us to arrange and express, in a language understood by all, the result of the researches made in the different countries."

From the results of my experience during the past six months, I am strongly of opinion that the only way to obtain results of a strictly comparative character would be to make an extended series of tests with the proposed standards on a four-way photometer, by which means one central light would

be tested simultaneously by four different standards. It would be highly desirable that the observations should be conducted by as many competent photometrists as possible, each of whom should have considerable preliminary practice with all the standards to be tried; as however competent an observer may be with a standard with which he is acquainted, he cannot possibly be expected to obtain the best results with an entirely novel apparatus. The desirability of this latter proposition is strikingly shown by the results of the tests made by M. Monnier with the English candle, the results obtained by that gentleman being evidently of an exceptional character. M. Monnier states that the normal carcel is equal to 8.3 English spermaceti candles, whereas, as I have stated, Mr. Sugg in 1870 made it equal to 9.6 candles, and I have recently found it to be equal to 9.41 candles. The wide divergence of M. Monnier's results from those of Mr. Sugg and myself, is only another powerful argument for the speedy settlement of the question.

In submitting these general conclusions and suggestions to the Society, I have not thought it desirable to encumber the question with tabulated statements of the results of numerous experiments, but I have rather desired to deal with the subject from a broader point of view—with general considerations instead of minute differences. It is most sincerely to be hoped that experts and inventors will dismiss all personal rivalry and join in a combined effort for effecting that which all admit to be so desirable. I would most earnestly plead with all to abstain from anything which might convey a personal reference beyond matters of fact. I am sorry to have noticed remarks which can never contribute one iota to the solution of a question of so pre-eminently difficult a kind as that of the standards of light. For my own part I have deemed it but just to the memory of one who is with us no longer, to put his proposal clearly before the public; I refer to the Keates lamp, and in doing so I have only discharged that which I felt to be a duty. Whatever may be the results of future work in this direction, I shall endeavour, as I have done in the past, to obtain undoubted evidence of the truth, and to uphold that standard which prolonged experiments shall show to be most trustworthy in all respects. Whether this standard be one of those now proposed, or some future device, is a matter of perfect indifference to myself, as I hope it is to others. The question is an international one, and if settled upon a broad and permanent basis, it will be lasting, and a credit in future ages to the present time.

*Note.*—Since the date of the above paper, the author has been instructed by the Metropolitan Board of Works to carry out a further series of experiments by means of a four-way photometer as recommended by him.

#### DISCUSSION.

The CHAIRMAN said they had to thank Mr. Dibdin for a most interesting and suggestive lecture on two very important subjects. The first part of the lecture, dealing with the use of the radial photometer in studying the distribution of light, appeared to him to be one which all would do well to pay more attention to, and particularly those who had the arrangement of lighting specially large buildings. As a rule, the great object of lighting a large building seemed to be to provide that the greatest possible amount of light should be thrown into the eyes of the unfortunate audience, and as much as possible introduced between them and the speaker or musician they were

listening to. If this was what was wanted, the arrangements approached nearly to absolute perfection. It seemed to him that the very simple idea of a radial photometer was the only method by which these common mistakes in the arrangement of lights could be avoided. Of course, if for private study people liked to have the light in their eyes no one could object; but he thought, even from a very little study of the elementary principles of how light fell—nothing near so perfect as Mr. Dibdin had given—people might save their eyes a great deal of weariness. One point which all would do well to bear in mind was that the eye was not a photometer, or rather that it was too perfect a photometer. The effect of a certain limited amount of bright light in closing the iris was most extraordinary; and very often the exceedingly dogmatic opinions which were heard as to the perfection or imperfection of particular lights, depended more on the question of whether the light was so arranged as to act upon the iris or not, as to any other cause. The light full in one's eyes contracted the iris, and diminished the amount of light falling on the retina from a less brilliantly illuminated surface. The question of the photometric standards was very interesting, and had several very important bearings. The mere question of whether gas was or was not an exact standard was only one detail. When we come to consider the relative advantages of different systems of lighting, or the relative value of different illuminating substances, this question was of the first importance; and it was only by such careful and accurate work as Mr. Dibdin had described that a conclusion could be arrived at.

Mr. VERNON HARCOURT said the radial photometer was really most admirably contrived, and calculated to do excellent service, and the determinations it afforded were very well illustrated by the length of the rays on the diagrams which had been shown, which brought before one, almost for the first time, a clear idea of the effects of shades and globes with which they had been so long familiar. Although he knew the effect of putting a shade over a lamp must be to throw more light downwards, and to diminish the amount of light spreading horizontally, he had never represented that effect to himself quantitatively, and could not have gained so clear an idea of it as he had gathered from Mr. Dibdin's diagrams. With reference to the standard of light, the point of greatest importance was that an effort should be made to have this question further investigated; and also that there should be some prospect of definite action being taken in the matter. The only reason, as far as he knew, for retaining the sperm candle in its present position was that it was specified as the standard by Act of Parliament, and must be continued to be used for the official business of gas testing until some change was made in the law. The Board of Trade instituted an inquiry some years ago, when a report was made to them, but, for some cause or other, no action had been taken upon it. He believed the reason was that which had stopped many more important matters—the exceeding difficulty of getting any measure through Parliament if there were any likelihood of opposition to it. Unless not only gas consumers, but gas companies also, were convinced that a change of standard was desirable, there was no likelihood of a Bill being brought forward on the subject which would pass through Parliament. Still, it was a most unsatisfactory state of things that they should be bound to use a standard of a most unscientific and unsatisfactory character, simply because it was connected with a large industry which had been established by law, and because there was great difficulty in getting the law

changed. He hardly liked to speak of the demerits of the candle; but all who had had to do with photometry must be aware that their best efforts were wasted in attempting to obtain exact results with candles. All the rest of their apparatus might be of a very perfect character, but so long as the standard with which other lights were compared was continually and miserably fluctuating whilst in use, the results could not be in any way satisfactory. It was wonderful that testing should be constantly going on with the object of seeing that the gas was up to the standard, and that men were working carefully and conscientiously at it, when they could not but have learnt quite early that their best endeavours were futile, and that the figures they were obliged to send in represented very little indeed. He hardly liked to enter on the question of the general merits of the various standards, as he was particularly interested in one of them; but he might say that until Mr. Dibdin's recent work was published he had no idea how excellently constant a light could be obtained from such a lamp as that which Mr. Keates had devised. He had formerly been prejudiced against standards in which the use of a wick was involved, because it would seem that variations in the plaiting of the wick, and variations arising from the difference in the length of time which had elapsed since the lamp was trimmed, together with small variations in the structure of the lamp, or position of the chimney, would lead to considerable variations in the amount of light it gave; but all such anticipations must yield to the facts of the testings Mr. Dibdin had recently produced, and reported to the Metropolitan Board, which showed that though these variations might occur, and the light might vary considerably, yet, by making a simple proportional correction for the amount of sperm oil consumed in the lamp, and assuming the amount of light given was directly proportional to the amount of oil consumed, and making the comparison between the corrected light and another flame from stored coal gas, it was evident that the light given to the lamp when the corrections were applied was of very great constancy. He was, therefore, fully convinced that this lamp deserved to take a high place amongst standards.

Mr. METHVEN said he was fully alive to the importance of the idea suggested by Mr. Dibdin of the desirability of having these standards more carefully and closely investigated; and it would be a grand thing when a standard was introduced which would put the sperm candle on one side altogether. With reference to Mr. Dibdin's recent experiments, he desired to refer especially to the results obtained by different operators. They could not but notice, in following the figures given by Mr. Dibdin, the great difference in the results arrived at by different operators; and this, he thought, was a very important point. His conviction was that the difference in results might arise in consequence of the different photometers with which they worked; and he was strongly of opinion that, before the question of a new photometer could be determined, it was absolutely necessary that some investigations should take place with reference to photometers themselves. He thought these differences obtained by different operators were in great part, if not entirely due to the disc which was at present generally used; and that if a little attention were devoted to this subject a better form might easily be introduced. He had been considering this question lately, but his investigations had not been extended sufficiently to warrant him in coming to any definite opinion. His impression was that much better results would be obtained if, instead of judging of the illumination of an opaque

spot in the centre of a greased paper, they had the opportunity of determining the depth of a transmitted shadow. He placed a piece of blackened tin at the same distance from the disc on either side—there being two pieces of tin on one side of the disc and one on the other—in order that the two shadows should not be thrown upon one another; and he found very great facility in determining the exact position of the discs by means of these transmitted shadows. It was much easier to arrive at the correct position of the disc by this means. When it was remembered that shifting the position of the disc 0.1 inch made a difference in the readings of  $1\frac{1}{2}$  per cent., it showed how carefully this point should be considered when the time arrived for the different standards to be investigated. If the operator had the screen obscured from his vision, he would have great difficulty in bringing the disc in half-a-dozen readings within 2-10ths of the actual position. This brought him to another point of great advantage likely to be derived from a high-power standard. In using such a standard the disc was brought down into the wider space, and the distance of 0.1 inch or even a  $\frac{1}{4}$  of an inch made very little difference in the result of the readings. This led him to consider the question of another form of photometer; and at present he was engaged on some experiments with one in which the standard and the disc were fixtures, and the light to be tested was movable. In a photometer of the ordinary length of the Letheby photometers—60 inches—he found the difference of the point on the bar of fifteen or sixteen candles was about  $1\frac{1}{2}$  inch. This  $1\frac{1}{2}$  inch divided into tenths of a candle was a perceptible distance, and he maintained that 0.1 inch, in the difference of light under those circumstances, would not make any serious difference. On the other hand, the distance upon the bar between fifteen and sixteen candle gas, on a 75-inch photometer, was only about half-an-inch, and the difference of 0.1 inch in placing the disc would make a difference of  $1\frac{1}{2}$  per cent. in the readings. Of course with a 60, 50, or 40 inch photometer the distance decreased, and a difference of 0.1 inch became very serious. He suggested having the standard and disc fixed, and the light to be tested movable. With a photometer of this kind you could measure 500 candles, or even an electric light, if you had provisions for taking it far enough away, the standard remaining constant all the time.

Professor FOSTER was very pleased to hear that Mr. Dibdin was continuing these investigations, particularly with regard to the reflection of surfaces, which was a subject of great importance at the present time, because extraordinary statements were made in the public press respecting the illuminating power of new lamps which were brought out from time to time. In many of the recuperative forms of lamps there was a reflector as well as the recuperating influence at work; and, before you could arrive at any scientific figures relating to recuperation as applied to illumination of the amount of light gained by reflection ought to be eliminated. He was referring to a number of lamps, which were familiar to gas engineers, in which the reflecting surface formed part of the lamp, and had a very marked effect; but the manufacturers dealt with the whole thing as a lump sum, showing the enormous amount of lighting power in a particular direction, not saying a word as to what reflection was doing, and what the true lighting power of the lamp might be. This was very important in considering special reflecting metallic surfaces made for a particular occasion, which might only last for that time, but would not do so much longer. With regard to the question of standards he was almost afraid to say anything on behalf of candles; but he

might remark that the first time he contributed anything to the *Chemical News* was in 1870, and it was with reference to sperm candles. There was an old proverb to the effect that threatened men live long; and he feared that the extraordinarily strong feeling in certain directions for a particular standard, only made the prospect of the life of the sperm candle still more favourable. It was extraordinary that something was not done to improve these candles. He did not know whether they were at all defined, but, if so, very little care was taken in their manufacture, so far as knowing the actual composition of the material, or the conditions of the manufacture. All were impressed with the importance of having a standard which could be produced under stated conditions. The air-gas standard was of this class; but still it was limited in many instances. They wanted a portable standard; and, for such purposes, the Keates lamp might be a very important function. Another important point was not to allow a great disparity to exist between the thing measured and the standard; and this seemed to have been overlooked in many instances. In dealing with large lamps, such as those of Sir James Douglas or of Mr. Siemens, a candle could scarcely be taken as a standard; in such a case the errors of observation became very marked, and, therefore, as a principle, there should be some comparison between the amount of light to be measured and the unit employed. The candle lamps devised by Mr. Harcourt might be admirable for measuring the gas in general use; but it would be very difficult to work with the standard for other special and technical purposes.

Mr. HARTLEY thought Mr. Dibdin must have said more than he intended when he said that, anterior to these testings, there had been no estimation of the amount of light at different angles. In his own vindication he must say that in the year 1881 he published a series of three articles in the *Journal of Gas Lighting*,\* one of which was especially devoted to the effects produced in the measurement of light at different angles. The difference between the measurements, then, and those of Mr. Dibdin consisted in this, that, wanting himself to know the difference in effect produced in lighting a vertical surface, he used a vertical screen, but, nevertheless, he had a photometer which enabled him to measure the amount of light from flames at any imaginable angle above the discs. Mr. Dibdin had gone a little in another direction, and was able to estimate the value of light coming upwards to the disc; but, as most of the lights in use were above the level of the eye, the most important determination was certainly that which dealt with an overhead flame. In ordinary estimations of light power, the light was measured horizontally, as when gas was tested for its illuminating power. At the same time he (Mr. Hartley) cited some experiments showing the effects obtained by reflectors of different forms, and gave illustrations of their effects. He then remarked that the screens placed in the base of an Argand flame generally made the light more soft and agreeable; but that the use of a reflector above cut off a tremendous amount of light. Again, he said, for the general lighting of rooms and offices, reflectors should be made so as to deliver the rays in a manner analogous to that which Mr. Dibdin had depicted. He claimed, therefore, the merit of having directed special attention to the necessity for measuring flames in various ways; and, in the same paper, drew attention to the fact, which did not seem to have been observed before, that,

\* See "Observations on Glass, as an Obstructor and Reflector of Artificial Light," by Mr. F. W. Hartley, A.I.C.E.; and *Journal of Gas Lighting*, Vol. xxxvii, pp. 54, 94, 130.

in dealing with flames at different elevations, it was very necessary that the angle should be regarded. Referring to the amount of light indicated in different directions by different burners, he said the diagrams were very beautiful; but the fact was known as far back, he believed, as 1826, to Mr. F. J. Evans, who made the first experiments with respect to flat-flame burners, and who announced that the edge of the flame yielded less light than the side. Since that time a number of others had observed the same thing. In 1881 he made a large number of tests with paraffin lamps, in which he referred to the effects produced from the flat sides and the edges. In this respect he differed from Dr. Redwood and his son; because he found the difference less than they did; and, although a gas man, he was quite ready to render justice to the lamps which he tried. Coming now to the various standards of light, he had been associated with Mr. Heisch in testing the standards under the authority of "The Gas Institute," and both of them, though most unwillingly, felt compelled to say something adverse to Mr. Harcourt's pentane standard. Mr. Dibdin had, during the evening, tried an experiment, with the view of showing that the Harcourt air-gas was not subject to vibration; but he should remark that, in their report, Mr. Harcourt and himself drew a distinction between the two kinds of standards—the lamp standard and the air-gas standard—and stated that it was the lamp standard which was specially subject to vibration. The lamp was now presented in a different form to that which they experimented with. It had then no top chimney, only one at the base; and the consequence was that it simply directed an upward current of air to the flame, which was more liable to vibration. M. Mourier, in testing candles, found the French lamp equal to about 85 candles; but Mr. Sugg and himself made it 93, and Mr. Dibdin 94, so that there seemed some difference in the usage of candles, or, perhaps, candles gave more light now than they formerly did. He had not had an opportunity of trying the Keates lamp at the time he was invited to do so; and afterwards he was not able to use it. He was surprised to find, in respect of the Methven standard, that, while Mr. Dibdin said it showed considerable variations, he found that, with a cut-off flame, which, after all, was little more than the Methven standard in another form, he got constant light. The Keates lamp was used with a cut-off flame; and, taking the Methven screen out, they were told that it would give a light of four or five candles at will. Now, if one flame could do it, why not another? Certainly the flame varied to some extent with the quality of the material burnt. But it had been proved that the quality of the material might differ to a very large extent; for it was shown by the Board of Trade investigations some years ago, that at least the difference of two or three candles might be caused by gas of different qualities, and yet the same light was yielded through the modern slot. He was decidedly at issue with those who advocated a high-power standard. He found it much more comfortable to use a comparatively low power than to use a high one, the effect on the eyes being less powerful. Again, it was a question whether with a high power the eye was not satisfied much more easily than with a low power; and, therefore, differences, which might exist, were not so easily discoverable. It was easy to weigh tons, but comparatively difficult to weigh fractions of a milligramme, and it seemed to him that the same thing held good with respect to photometry. Differences were really found when standards of comparatively low power were used, which were undiscoverable with standards of high power. This consumption would apply to what Mr. Methven

had said with regard to the advantages of wide spaces. This question would, no doubt, in the end be settled under the direction of a Parliamentary Committee, when all those interested in the matter would be called together. It was certain that, up to the present time, there was no bitter antagonism on the part of any of the operators engaged in these investigations. They were all anxious to arrive at the truth; but circumstances rendered the determination difficult, if not impossible, but when they all got together, they might, perhaps, arrive at it. Mr. Foster had touched on the question of reflection, and he also wished to emphasise the importance of this matter; and, when burners were being tested, it had been specifically stated when reflecting surfaces were used, and it had also generally been shown what the effect of these surfaces was within a certain area. Mr. Foster was certainly right in saying that there ought to be specific statements as to the effect of reflectors.

Dr. PERKIN said he was not specially conversant with this matter; but, in working a polariscope, he had found that when the light was very strong there was a difficulty in getting accurate readings, and if it were very weak it was very trying to the eyes. He should therefore think the happy medium was the thing to be aimed at in most cases where the eyes were used.

Dr. PERCY FRANKLAND said it seemed to him that photometric observations with reflectors must be considerably misleading, unless the precise circumstances of the case were always given; because with certain kinds of reflectors you would get an entirely different observation according to the length of the photometer. If the source of light were placed at different distances from the screen, that would give entirely different readings to what it would if placed at another distance. The length of the photometer, in fact, was the actual factor in the determination. In all cases where burners were tested the reflectors should be discarded altogether, and special statements made with regard to the effect of particular reflectors which were recommended. With regard to the standard of light, he had generally used candles and a Methven screen, but it seemed to him a very important matter to have a standard of light at any rate approximately equivalent to the light to be tested. This was really a mathematical question. It was evident that when the source of light and the standard were nearly equal, any deviation between them would give readings very much larger than in the opposite case. It was like making an analysis with a large quantity of the substance; and they all knew how much more accurate the results were when the quantity of the substance employed was large than when it was very small. Of course, there was also the question which was most agreeable to the eye; and there could be no doubt there was a certain happy medium in that matter. You could not for a long period of time look at a source of light like a Keates lamp with the same comfort that you could look at the standard candles or the Methven screen. With regard to Sugg's ten-candle standard, he was much interested to hear that the light remained the same in spite of changes in the richness of the flame. He had had occasion, recently, to take the illuminating power of gases of great richness, and when doing so had been struck by the large space of blue flame at the base when burned in the ordinary Argand burner; but he had not been prepared to hear that this increase in the blue portion of the flame was so exactly in proportion to the richness of the gas.

Mr. WHITLEY WILLIAMS exhibited a lamp to which his attention had been drawn by Mr. Frederick Siemens, having been devised by Dr. Von Hefner Altneck, for the purpose of measuring the electric light. It possessed many of the advantages of Mr. Vernon Harcourt's pentane standard, but, in some respects, it was much more simple. It was essential, with a photometric standard, that the substance burnt should be of absolutely definite composition; and it was equally requisite that the amount of light given by it should be in exact proportion to the amount of substance burnt. In this case a sufficiently complete and extensive series of experiments had not yet been made to demonstrate this completely, but he had seen enough to be able to say that the light was an extremely good one—in fact, enormously better than that given by standard candles. These candles had been almost universally condemned, but it had always appeared to him remarkable that although enormous pains were taken with the apparatus, very little pains should be taken to control the standards they had to use. He had been obliged to reject more than one-third of the candles supplied to him, and one which he had brought with him was utterly unfit for use, the wick being out of the middle of the candle. It seemed to him rather remarkable that, whilst they were compelled by Parliament to use these candles as the standards, there were no conditions imposed as to the way in which the candles should be made. A great deal also depended on the way in which the candles were burnt. This lamp was made to burn amyl acetate. A tube of German silver, of a given thickness and diameter, was inserted in the lamp, and the thickness and construction of the wick did not materially matter. The flame was regulated to the height of two pointers, and could be very easily adjusted. After about ten minutes' burning the flame remained constant for eight hours with hardly a shade of difference, and when it had burned for this time the wick itself showed no signs of charring. That arose from the fact that the boiling point of amyl acetate was enormously below that at which the wick even began to be charred, or browned, and in that respect, at all events, the lamp was an admirable one. It was not by any means absolutely necessary that the amyl acetate should be particularly pure. If butyl acetate was taken, the next lower homologue of the series, the amount of light given out by the lamp was 99 of that given when pure amyl acetate was used. He had suggested to Mr. Siemens that the lamp should be made simpler, as it now weighed nearly 1 kilo., and he believed it might then be made very serviceable. Dr. Von Altneck was very anxious to correlate this with the English candle in use, and he found that by adjusting the height of the flame to about 40 mm. from the edge of the metallic tube the light was almost exactly equal to English sperm candles. He had used this from time to time in the intervals of testing the gas of the Metropolis, and the results very fairly agreed. He found one reading always came within  $1\frac{1}{2}$  per cent. of the mean of 300 tests.

Mr. DIBBIN, in reply to Mr. Methven, said the differences observed by different operators were not due to their having used different photometers, the tests to which he referred having all been made on one photometer and one disc. Mr. Hartley seemed to think he was under the impression that no photometer had been used for testing angular rays previous to the introduction of the radial photometer. It was quite true that Mr. Hartley made some tests in 1881, but they were made on the vertical disc; and he had before pointed out to the Society, and might point out once more, how important the

position of the disc was. If the light were above the vertical disc, the horizontal rays would have no value. It was Mr. Hartley's "Universal" photometer, as altered by Professor Foster and himself, which led to the present form. He had not the slightest doubt that, as Mr. Hartley had said, the difference between the light given by the edge and flat side of a flame had been proved before; but he thought it would be interesting to make some further tests for his information, if not for others. He did not claim any special merit or novelty in that matter. He hoped the time would soon come when Mr. Hartley would be able to make tests with the Keates lamp. He should remark, however, that the Keates lamp with a screen was not the lamp as devised by Mr. Keates, which was a 16-candle lamp. The screen was a suggestion of Mr. Suggs; but he (Mr. Dibbin) did not much approve of it, although he believed it had been found to give very good results. Variations in the character of the flame, which was not of any importance when the total consumption of oil was taken into account and the corrections made, were very serious when only a small portion of the flame was taken, and no correction made for the consumption of oil. Dr. Percy Frankland had pointed out a very important matter in connection with reflectors. It was, no doubt, necessary, in all such cases, that the length of the photometer bar should be taken into account; and, in any comparative experiments with different screens, the same length should be used in all cases. It would be ridiculous to test one reflector on a 50-in. bar, and another on a 200-in. bar. What he claimed for the radial photometer was that it gave the opportunity of testing to every degree; but, in the diagram showing the effects of the compound reflector, he had only taken one or two points to give the general effect, showing whether the maximum light was up, down, horizontal, or in what direction. In regard to a powerful flame being very trying to the eyes, it, no doubt, was so, if the operator were foolish enough to stare at the light. But, in making photometric observations the operator only looked at the light occasionally to see if it was burning properly, and then he should only do so through coloured glass. The observer could not read the disc properly if he looked at the light. The eye should be carefully shaded in every way, and operators who were not careful about this matter would never get reliable results.

The CHAIRMAN then proposed a vote of thanks to Mr. Dibbin, which was carried unanimously, and before the proceedings terminated, the latter gentleman showed and explained the action of the radial photometer.

SIR HENRY ROSCOE IN THE CHAIR.

## ON THE ESTIMATION OF TANNIN.

BY BERTRAM HUNT.

IN the following memoir I propose giving a modification of the method of estimating tannin by permanganate. The modification consists in the method of precipitating the tannin previous to the titration for "matters oxidised other than tannin." Procter, (*Journ. Soc. Chem. Ind.* iii. p. 82), in order to precipitate the tannin, adds to 50cc. of the tannin solution 25cc. of gelatin solution and 10cc. of dilute sulphuric acid. He then saturates the liquid with salt, adds a little kaolin, and shakes thoroughly. He thus precipitates all the tannin, and almost all the gelatin present, and on filtering gets a clear bright filtrate. I have found, however, that in order to get a clear, tannin-free filtrate, it is unnecessary to saturate the liquid with salt, and that, in the case of materials containing any considerable quantity of gallic acid, the results are too high owing to the precipitation of some of the gallic acid. The following method gives a liquid which filters easily, and the filtrate is perfectly clear, and free from tannin. 50cc. of the tannin solution are run into a small dry flask; to this 25cc. of a fresh filtered solution of gelatin (2grm. per 100cc.) are added, and the flask shaken. 25cc. of a saturated solution of common salt, containing 50cc. of strong sulphuric acid per litre, are now added, and about a teaspoonful of pure kaolin or baric sulphate. The flask is now thoroughly shaken for a few minutes. The solution filters easily and quickly, and the filtrate is clear and bright.

In order to compare the two methods, the following experiments were made:—A solution of "pure tannin" was made of a strength of 10grm. per litre. On analysis this solution gave, by Procter's method, 0.8940grm., and by the modified method 0.8937grm. tannin per 100cc. These numbers are calculated on the supposition that 63grm. oxalic acid = 41.57grm. gallo-tannin. To 9 volumes of this solution was added 1 volume of a solution of 10grm. gallic acid in 1 litre water. On analysis, this second solution gave, by Procter's method, 0.8176grm., and by the modified method, 0.7956grm. tannin per 100cc. To 8 volumes of the tannin solution were now added 2 volumes of gallic acid solution. The resulting solution gave, by Procter's method, 0.7399grm., and by the modified method, 0.7111grm. per tannin per 100cc. These results prove, I think, the precipitation of gallic acid along with tannin in Procter's process, and the following results confirm it. A solution of 5grm. gallic acid per litre water was made. On going through the process of precipitating tannin by Procter's method with 50cc. of this solution, it was found that 18.48 per cent. of the gallic acid was pre-

cipitated, while by the modified method only 3.18 per cent. was precipitated. When the gallic acid solution was of a strength of 1grm. per litre, by Procter's method, 17 per cent. was still precipitated, and by the modified process only traces.

As regards the titrations with permanganate, the method of working recommended by Procter gives perfectly satisfactory results. With practice, results of duplicate titrations, agreeing to 0.5cc., can always be obtained.

A good method of extracting the material to be tested, is to weigh out an amount of substance rather less than 20grm., extract by boiling half-an-hour or so with about a litre of water, wash and make up the clear cold solution to a strength corresponding to 10grm. per litre. For the estimation of the "total matters oxidised by permanganate," it will be found that, if some of the solution of above strength be diluted 10 times, 10cc. will be a convenient quantity to titrate along with 20cc. of indigo solution. For the estimation of "matters other than tannin," if the material contains more than 45 per cent. of tannin, it is advisable to take only 25cc. instead of 50cc. of the tannin solution, and 50cc. instead of 25cc. of the saturated solution of salt, the amount of gelatin solution added being the same (25cc.). The gelatin solution must, in all cases, be freshly prepared and filtered.

In the case of gambier and allied materials, precipitation by gelatin and salt does not remove from solution all that is of "tanning value," as the following experiment shows:—200grm. cubegambier were shaken till dissolved in a litre of water at 60° C. The solution was then allowed to stand 24 hours, and the clear liquid syphoned off. The sediment was stirred up with some cold water, and again left to settle. This treatment was repeated till the clear liquid gave no precipitate with gelatin. 10cc. of the clear liquid were then placed in contact with 5grm. of "pure dry skin." By titrating the liquid with permanganate before and after contact with the skin, it was found that 68.66 per cent. of the "matters oxidised by permanganate, as oxalic acid" had been absorbed by the skin. The best substance for abstracting the tannin from solution in the case of this material is pure dry skin shavings or powder; and if the skin be prepared in the following manner, constant and concordant results can be got:—Selected pieces of pelt, as they come from the "late," and are ready for the tanpit, are freed from adhering flesh, and soaked for an hour or so in water slightly acidulated with acetic acid. The pieces of pelt are then thoroughly washed with frequently changed quantities of distilled water till free from acid. They are then soaked for 24 hours in clean methylated spirits. After squeezing, they are soaked in "alcohol distilled over lime" for another 24 hours. The pieces are now dried thoroughly at a low temperature, and brought to a state of fine division by planing or otherwise. To perform an analysis 5-6gm. of the dry pelt are put into a small flask, with about 100cc. of the gambier solution, containing 10grm. gambier per litre. The solution is kept in contact with the pelt for at least 12 hours, and the pelt then filtered off. The filtrate is then titrated for "matters other than tannin" in the usual way.

As there appear to be few reliable analyses of tanning materials by the permanganate method published, I give below some results got by me in testing different materials. The tannin was estimated both by Procter's method and by the modification described in this paper. Both methods were worked simultaneously with the same solution of the respective tanning material, so that the results are strictly comparable. The filtrates from the gelatin precipitates were in every instance tested for tannin, but in no

instance was any found. They were also tested for gallic acid by potassic cyanide solution (S. Young, *Chem. News*, 48, 1234, p. 31), and in the case of those materials containing a relatively large amount of "matters oxidised other than tannin," the colouration, in equal bulks of solution, was distinctly less intense in that from which the tannin had been precipitated by Procter's method than in the other.

On referring to the following table of analyses, it will be observed that the difference in the percentage of tannin found by the two methods is greatest in the case of those materials containing a relatively large amount of "matters other than tannin oxidised by permanganate."

The "total extract" in the following table was determined by evaporating a portion of the tannin solution to dryness in a small porcelain basin and drying the residue at 110° C. The "insoluble matter" was also dried at 110° C.

## DISCUSSION.

The CHAIRMAN: You are all aware that there are considerable difficulties in the determination of these very important substances. The subject has already received the attention of our Society in a paper which was read by Mr. Procter before the Newcastle Section, and which is published in our Journal. Mr. Hunt's method seems to be an improvement on Mr. Procter's, and I hope it is a method which can be entirely relied upon.

In reply to several questions by the Chairman, Mr. HUNT said: Gambier and similar materials contain a large proportion of "catechin" or similar bodies which are not precipitated by gelatin, but are of tannin value as they are absorbed by skin. It is true that these bodies are precipitated almost completely by the addition of salt and acid to the solution, but matters of no tannin value are also

Absorbed by  
Dry Pure Skin.

precipitated. Skin does not thoroughly absorb tannin, at least in many cases it would take fully twenty-four hours. In the case of gambier it is absorbed very quickly.

Mr. GRIMSHAW: Although I have not been able myself to do much in the way of research upon the estimation of tannin materials, I have had at times a number of such analyses to conduct, and have almost always adopted Mr. Procter's modification of Löwenthal's method. I have certainly found that something interfered with satisfactory results being obtained, but it did not occur to me that this was owing to the different quantity of salt used. I should like to ask Mr. Hunt two questions in relation to tannin materials. The first is as to whether he has made any experiments with regard to ascertaining if there is much difference between the results which he gets when the tannin is abstracted by skin or similar material, and by re-drying and weighing the horn, skin, or pelt itself? Of course we are not properly acquainted with all the materials which are taken up in the process of tannin, and it would therefore be of great interest and value to compare the valuation of the material by chemical analysis with that represented by the increased weight of the skin itself. The second question I should like to ask is whether Mr. Hunt could give us a little information as to how he selects and prepares the indigo which he uses as an indicator? Of course it is pretty well known that certain descriptions of indigo are not equally suitable for showing the point at which oxidation is finished. Some samples you may take, particularly those which give a brownish shade, interfere with the determination, and I find it difficult to get an indigo which will act satisfactorily in showing the end of the oxidation of the tannin materials.

Mr. HUNT: As regards the first question, I have made a series of experiments, and have found in many instances the results agreed very well. Procter's results were always too high. In some instances the results by my method were lower, and in others slightly higher, than those got by absorbing the tannin with skin.

Mr. GRIMSHAW: There is also a method of forcing the liquor through one or more skins. It is a modification of Hammer's method, and was introduced by Müntz and Ramsbacher with a special apparatus for the purpose.

Mr. HUNT: For most materials the method is perfectly useless. With some materials the skin only absorbs a portion of the tannin, as proved by Procter and others. Gambier is the only material for which this method is of any use at all. With regard to indigo, I get the best indigo carmine and dissolve it in hot water, and the strength I use is about 5grm. per litre, with 50cc. strong sulphuric acid, and this has given satisfactory results. You should test the indigo, and reject any that gives the brown colour with permanganate to such an extent as to interfere with the end reaction. Löwenthal, the originator of the permanganate process, used a solution of salt and gelatin to precipitate the tannin. Procter adds a solution of gelatin, then dilute acid, and then saturates the liquid with salt, and thus gets a liquid easily filtered. In my process I add gelatin solution to precipitate the tannin, and then a certain proportion of a saturated solution of salt containing acid, and thus get a liquid which filters as easily as by Procter's method, but the gallic acid present is not precipitated, or at any rate to a far less extent than in the case of Procter's method.

Mr. SIEBOLD: I should like to ask Mr. Hunt whether in his determination the tannin alone is determined unaccompanied by colouring matter? I

have made many determinations of this kind by means of gelatin without the addition of salt, and have always observed that a considerable portion of the colouring matters present in such substances as sumach, myrabolams, divi, valonias, galls, etc., are precipitated along with the tannin, while the filtrates from the gelatin precipitates appear comparatively colourless. When I worked with a solution of pure tannin, and then repeated the experiment with the addition of colouring matters free from tannin, there was always a notable difference in the result, more gelatin solution being required in the latter case than in the former. In the case of divi and similar substances rich in colouring matter, the amount of tannin thus found may be as much as 50 to 100 per cent. in excess of the actual proportion of pure tannin present. As already stated, I have never applied salt in these determinations, but have simply used a standardised gelatin solution containing a minute proportion of alum. The liability to error arising from colouring matters is, however, not confined to the gelatin process, but is shared by almost all the other technical methods for the estimation of tannin. I have obtained fairly accurate results by using organic alkaloids as precipitants; but this method may be objectionable on account of the expense. A good practical method of determining tannin in the various materials named remains, in my opinion, still a desideratum.

Mr. HUNT: In Procter's process the filtrate from the tannin and gelatin is nearly colourless. Alkaloids could not be used, as the results are too low. The precipitate of the alkaloids is slightly soluble, Neubauer having shown that even when excess of cinchonine was added the filtrate contained tannin.

The CHAIRMAN: Does your method give the results?

Mr. HUNT: The "permanganate value" of the tannin in each material is different. For instance, the tannin of gallnuts is quite different, as regards its action on permanganate, to that of oakbark. The tannin of sumach most nearly resembles gallo-tannin.

The CHAIRMAN: How can you compare them?

Mr. HUNT: I always give my results in terms of oxalic acid, as recommended by Procter. It is useless to try to compare the relative values of different tannin materials. It is only possible with certainty to compare different samples of the same material.

The CHAIRMAN: That seems to indicate an acknowledgment that the method does not apply to different materials.

Mr. HUNT: There is no method which does that.

Mr. SIEBOLD: It is certain that all these methods estimate more than the tannin present, and that the results are therefore too high. I cannot endorse the unfavourable opinion expressed by Mr. Hunt relative to the alkaloid processes, and am inclined to think that the lower numbers obtained by them are less due to the solubility of the precipitates than to the greater freedom of the latter from colouring matters. For the purposes of the tanner, the gelatin process, as well as some of the other methods in common use, may perhaps be regarded as more satisfactory than for the purposes of the dyer and printer, inasmuch as the colouring matter which renders the tannin estimation too high passes into the leather along with the tannin. In fact a certain body of colour is desired by the tanner, and so long as this is not excessive and not of an unsuitable shade, it is a valuable constituent of the materials employed in tannin. It ought to be well understood that none of the analytical methods alluded to by Mr. Hunt will give the actual proportion of pure tannin; and that for this reason dyeing experiments will often give more valuable results than a chemical analysis.

Mr. HUNT: By my method there is less "extractive" precipitated than by Procter's. In Procter's method the complete saturation of the liquid with salt undoubtedly precipitates a considerable amount of "extractive" along with the tannin. In the method given to-night, as the tannin liquid is not saturated with salt, less "extractive" is precipitated with the tannin, though, of course, I cannot say for certain that tannin only is precipitated. It is unfortunate that I have been unable to give you in a large diagram the full list of analyses, which would, I think, have shown you the difference between the two methods. If there is no salt or acid added it would be almost impossible to filter the solution.

Mr. SIEBOLD: The extent to which these colouring matters and vegetable extractives impair the result is much larger than is generally supposed. In some instances in which I ought to have found about 10 per cent. of tannin, the analysis showed double that amount and more, which shows at once how utterly unreliable these tests are when applied to such substances as I have before named.

Mr. HUNT: As regards the precipitation of colouring matters, do you use alum with the gelatin, and did you prove that alum had no part in the precipitation of the colouring matter?

Mr. SIEBOLD: I feel satisfied that the precipitation of colouring matters by gelatin, to which I have repeatedly alluded, is not due to the small proportion of alum used in my experiments, but would occur equally just the same in its absence.

Mr. SANSONE: I beg to endorse Mr. Siebold's remarks with regard to the ordinary methods of estimation of tannin not being reliable. I always use comparative methods, which are the only ones to be relied upon. First of all I ask myself what is the tannin to be used for? In the case of sunnch, we know it is used by dyers, and we must have regard to the amount of work to be done. Suppose we take some cotton and prepare it with a solution of acetate of iron; we dry it and expose it to the air, and then by passing it through a whitening bath we complete the fixation of the oxide of iron on the fibre. Now, if we take a weighed quantity of this cotton and dye it in a bath containing tannic acid, we form a grey colour on the fibre. If we take two or three different samples which are treated in a similar manner, we can judge by the depth of shade which of the samples is the strongest; and if we take the different samples in relation to their price, we have at once a comparative method—that is, the sample which will give the deepest shade on the cotton prepared with iron will be the strongest. There is another plan which could be followed, and which also gives good results. If cotton be mordanted with different samples of tannic acid, which are to be tested and left over night in the bath, then next morning passed through a bath of tartar emetic and washing, we have here several patterns which can give us an indication of the strength of the tannic acid, especially if the quantity of the tannic acid had been calculated in proportion to the price. If we dye all these patterns in any aniline colour, say magenta or methyl-green, the pattern which had been prepared with the strongest tannic acid will give the deeper shade, and therefore in this case also you have a comparative method, and this method can be made even more exact by soaping these dyed patterns, and the colour which remains on the fibre will give an indication of the strength of the tannic acid employed.

Mr. GRIMSHAW: How would Mr. Sansone arrive at the value of a material used for tanning leather by the comparative process he mentions? Such a method as he alludes to would no doubt be a good criterion of the value as a dye, but is not applicable

to its use for tanning, where many different constituents are absorbed by the leather or skin, and comparative "tanning" would be a very different thing from comparative "dyeing."

Mr. SANSONE: The method I mentioned is only valuable to dyers of cotton; but for leather I should think a comparative method might also be tried.

## NOTE ON THE DESTRUCTION OF TANNIN BY BOILING SOLUTIONS OF GAMBIE.

BY BERTRAM HUNT.

GAMBIE, as you are doubtless aware, is an extract from the plant *Uncaria Gambier*, and is imported in large quantities from Singapore. It occurs in the market in two forms—"bale" and "cube"—of which the latter is the more valuable, being drier than the "bale," and offering less opportunity for fraudulent adulteration. It is used largely in tanning, the strong liquor made by dissolving about four pounds per gallon in boiling water being added in suitable proportions to the tan liquor in the pits. The usual method of dissolving gambier is to put it in a tank with the requisite quantity of water, and boil up with naked steam till the whole is melted. The solution has to be used while hot, as if allowed to cool it "sets," and becomes semi-solid. During the boiling the colour of the liquor becomes very dark, and there is an evident loss of tannin. It occurred to me that it would be of interest to estimate the amount of this loss, and I have done so with the following results. 400grm. of cube gambier were placed in a flask, with a litre of water. The flask was then connected to an inverted condenser, and the contents heated to boiling and boiled gently for 20 minutes. 400grm. of the same gambier were now placed in a stoppered test-mixer, with a litre of water heated to 60° C., and the test-mixer shaken till all the gambier was dissolved. The two solutions were allowed to stand over night, and the clear liquor then analysed, with the following results:—

### WATER AT 60° C.

Tannin, as oxalic acid .....	15.902grm. per 100cc.
Other matters .....	4.300grm. "
Total Extract .....	24.200grm. "

### BOILED.

Tannin, as oxalic acid .....	15.524grm. per 100cc.
Other matters .....	4.536grm. "
Total Extract .....	24.500grm. "

The experiment was repeated under the same conditions, with the exception that the boiling in the one case was continued for 40 minutes. In this experiment 0.504grm. tannin per 100cc. were destroyed. These results show that when working under conditions more favourable for the preservation of tannin than are the case in practice, there is a considerable loss of tannin. Without taking into consideration the loss incurred owing to the darkening of the colour (which, with tanners, is an important point), if the gambier liquor is made by dissolving four pounds in one gallon of water, and gambier containing 50% tannin at 26s. per cwt. be taken, it will be found on calculating that the value of the tannin destroyed comes to a fraction over £1 for every 1000 gallons of liquor made.

## NOTES ON THE TESTING OF DYEWOOD EXTRACTS, AND SIMILAR PREPARATIONS.

BY L. SIEBOLD.
